Abstract

The Dry and Central Mixedwood subregions cover nearly 40% of the province and are dominated by aspen, jack pine on coarse textured soils and black spruce, willows and sedges in the poorly drained areas. The vegetative communities in these subregions are important because they provide summer range for livestock, prime habitat for many species of wildlife, productive watersheds, recreational areas and timber harvesting. Despite the importance of these vegetation types there is little information on their ecology. The lack of information makes it very difficult to develop management prescriptions for multiple use. As a result guides like this and "Ecosites of Northern Alberta" (Beckingham and Archibald 1996) are being developed to provide a framework that will easily group the vegetative community types. It is hoped these classification systems can be used by field staff to assess the ecology of the sites and develop management prescriptions on lands within each region.

This guide represents the analysis of 349 grass, shrubland, conifer and deciduous plots described in the Dry and Central Mixedwood subregions. These types are split into:

Dry Mixedwood subregion

Introduction

The province of Alberta is covered by a broad spectrum of vegetation regions from prairie in the South, to alpine vegetation in the mountains and dense forests in the Central and Northern parts of the province. These broad vegetation regions have been classified into 6 regions and 20 subregions (Dept. of Environmental Protection 1994). Each of the 20 subregions consists of groups of plant communities which are influenced by environmental conditions and human impacts. Intensive management of these regions requires the ability to recognize the vegetative communities that have similar productivities and respond to disturbance in the same way.

The vegetative communities in the province of Alberta are highly regarded by most resource managers for their ability to provide a wide variety of benefits. They are a classic example of multiple use land, providing summer range for livestock, prime habitat for many species of wildlife, productive watersheds and recreational areas. Despite the importance of these vegetation types there is little information on their ecology. The lack of information makes it very difficult to develop management prescriptions for multiple use.

The purpose of this guide was to develop a framework that would easily group the plant community types utilized by livestock in the Dry and Central Mixedwood subregions of the province. This guide combines the Low and Mid Boreal Mixedwood ecoregion guides done by Sundquist and Willoughby in 1993 and 1994.

It is hoped this classification system can be used by field staff to assess the ecology and carrying capacity of the sites, in order to develop management prescriptions on lands within each region. This guide supplements the work done by Beckingham and Archibald (1996) on the forested community types in the Boreal Mixedwood of northern Alberta. Their guide is a good description of the forested community types found within the subregion, but it does not include forage production values and carrying capacities. It also does not provide a description of the native shrubland and grassland communities which are utilized extensively by livestock in these subregions.

Climate

Dry Mixedwood subregion

The Dry Mixedwood subregion represents a transition between the Central and Peace River Parklands and the Central Mixedwood subregions. This subregion occurs in three areas of the province. One section is located between the Central Parkland and the Central Mixedwood subregions in the southern portion of the boreal forest and includes the Onion Lake, Athabasca, Westlock plains and Whitefish and Frog Uplands ecodistricts (Strong and Thompson 1995). A second area is located immediately east of Edmonton in the Cooking Lake upland ecodistrict. The third and largest area parallels the Peace River in northwestern Alberta from Grande Prairie

to Fort Vermillion and includes the Debolt, Dunvegan, Falher, Smoky, Grimshaw, Manning, High Level and Boyer plains ecodistricts (Map 1).

Mean summer temperature averages 13.8°C and winter temperatures average -10.5 °C, which is somewhat warmer than the Central Mixedwood subregion and somewhat cooler than the Parkland subregions. Mean annual precipitation averages 380 mm which is drier than the Central Mixedwood, but wetter than the Parkland subregions.

The reference plant community in this subregion is dominated by Aspen, with a variable understorey dominated by rose, pea-vine, beaked hazelnut, saskatoon and marsh reedgrass. Jack pine stands are found on well drained, coarse-textured parent materials and poorly drained sites are dominated by black spruce, willows and sedge species.

Central Mixedwood subregion

This subregion is the largest in the province covering over 210,000 km² or nearly 32% of the province (Strong and Leggat 1992)(Map 2). Mean annual summer temperatures average 13.5 °C and winter temperatures average -13 °C, which is somewhat colder than the adjacent Dry Mixedwood subregion. Annual precipitation averages 397 mm of precipitation which is wetter than the Dry Mixedwood.

The modal plant communities are vegetated by aspen and balsam poplar with understories composed of a variety of herbs and deciduous shrubs. White spruce and balsam fir are the climatic climax species but are not well represented because of the frequent occurrence of fire. On dry, well drained, coarse-textured soils jack pine dominates and the poorly drained sites are dominated by black spruce, willows and sedge species. These reference communities are very similar to the Dry Mixedwood subregion, but the drier conditions of the Dry Mixedwood favours the formation of a number of native grassland communities, which are not found in the Central Mixedwood.

Map 1. Location of the Dry Mixedwood subregion in Alberta

Map 2. Location of the Central Mixedwood subregion in Alberta

Methods

A community type approach (Mueggler 1988) to classification was chosen in preference to the habitat type approach (Daubenmire 1952) or ecosystem association approach (Corns and Annas 1986) because of the lack of understanding of the successional sequences of the communities. Community types are aggregates of similar plant communities based upon existing floristics regardless of successional status (Mueggler 1988). Community types are what is actually seen in the field. After defining the community types, they then can be linked to the ecosystem associations developed by Corns and Annas (1986) and Beckingham and Archibald (1996). In the mean time community types can be used as the basis for mapping and range management planning.

Individual plots were initially classified within a forest region using cluster analysis (SAS) and ordination (DECORANA, Gauch 1982). These types were described in individual carrying capacity guides for each forest. This led to differences in classification of the same types between forests, particularly for deciduous forest types. In an effort to standardize the community name and gain some understanding of each community types ecology, all plots sampled in each forest were reclassified. As the study progressed it became quite evident that there were differences in the productivity of the communities between subregions. As a result, it was decided to develop the classification within the subregion framework. A subregion is a geographical area that has broad vegetation zones combined with climatic data. As a result, the vegetation within each subregion is strongly influenced by the climatic conditions.

Sampling for this guide occurred within the Dry and Central Mixedwood subregions . This guide outlines the preliminary classification of 349 plots.

The procedure for inventory followed the Range Survey Manual (1992) and uses the MF5 form. A plot consisted of a 10x10 m macroplot and ten randomly selected 1x1 m microplots to record the canopy cover of shrubs and ten nested 20x50 cm microplots to record the canopy cover of forbs and grass. At each macroplot a 50x100 cm was clipped and separated into trees, shrubs, forbs and graminoids, oven dried and weighed. The recommended stocking rate is based on 25 percent of the total production for forested types and 50% total production for grass and shrubland types and the fact that one animal requires 455 kg of dry weight material for one month of grazing.

How to use the guide

First decide what subregion you are in. Then decide the appropriate category the community type is in within each subregion. If the area has been cleared of trees, broken, and seeded down to tame forage species such as timothy or creeping red fescue, the community will be in the TAME GRASS category. If the area does not have an overstory tree canopy and has not been cleared and broken, the community will fall under the NATIVE GRASS and SHRUBLANDS category. The DECIDUOUS category includes all plant communities that are dominated by deciduous tree species. Communities which have begun to undergo succession from a deciduous to a conifer dominated overstory with an overstory cover greater than 15% for both deciduous and coniferous species fall into the MIXEDWOOD category. Those communities

dominated by a conifer overstory, White spruce, Black spruce or Jack pine are classified in the CONIFER category. Three plots were sampled in deciduous cutblocks. These plots were included in the deciduous category under deciduous cutblocks.

In order to understand how the community types in this guide are related to the ecosites and ecosite phases outlined in “Ecosites of Northern Alberta” (Beckingham and Archibald 1996), the community types in this guide are arranged by ecosite and ecosite phase (Table 1). **Ecosites** are defined as ecological units that develop under similar environmental influences (climate, moisture and nutrient regime). An **ecosite phase** is a subdivision of the ecosite based on the dominant species in the canopy. Table 1 is a reproduction of Figure 11 in the Ecosites of Northern Alberta guide with the community types in this guide highlighted. For the most part the ecosites and ecosite phases are the same, particularly for the forested community types, but a number of new ecosites had to be created for the grass and shrubland community types (Table 1). These included (dd)(mesic/medium) purple oatgrass/california oatgrass, (bb)(submesic/poor) grassland/shrubland and (aa)(subxeric/medium) grassland. The “Grazing succession” category (Table 1) outlines the successionl sequence the community type will undergo with increased grazing pressure. DM refers to Dry Mixedwood subregion and CM refers to Central Mixedwood subregion.

In the rest of the guide the dominant plant species, canopy cover, environmental conditions, response to grazing, forage production and carrying capacity of the various community types for the Dry and Central Mixedwood subregions are outlined.

Results

The analysis of the 349 plots distinguished 90 community types in the two subregions. These types were split into 4 categories within each subregion:

Dry Mixedwood subregion

DMA. Native grass and shrubland	13 types
DMB. Tame grasslands	8 types
DMC. Deciduous community types	16 types
DMD. Mixedwood and Conifer community types	9 types

Central Mixedwood subregion

CMA. Native grass and shrubland	12 types
CMB. Tame grasslands	7 types
CMC. Deciduous community types	15 types
CMD. Mixedwood and Conifer community types	10 types

The dominant plant species, canopy cover, environmental conditions, forage production and carrying capacity (when available) are outlined for each community type.

Table 1. Ecosites, ecosite phases and plant community types for the Boreal Mixedwood subregion (adapted from Beckingham and Archibald 1996)(highlighted community types are described in this guide, non highlighted communities are outlined in guide to “Ecosites of Northern Alberta”)

DRY MIXEDWOOD SUBREGION
GRASSLAND AND SHRUBLAND COMMUNITY TYPES

Photo 1. The Western porcupine grass-Sedge/Fringed sage community is found throughout the Dry Mixedwood subregion on the south-facing slopes of the Smoky, Wapiti and Peace Rivers. This community provides early spring forage for both wildlife and cattle.

Photo 2. This picture represents the transition from sedge-marsh reedgrass meadows to willow sedge dominated community types. These community types provide a large amount of forage, but the moist conditions limit their use by livestock.

DM - NATIVE GRASS AND SHRUBLAND COMMUNITIES

The Dry Mixedwood subregion represents the transition between the Boreal forest and Parkland subregions. Aspen Parkland-like vegetation can develop where site conditions or drought conditions occur in combination with the driest climatic conditions (Strong 1992). The Grande Prairie area is an example where a number of these conditions occur. It is within this area that a number of native upland grassland community types have been described. On steep, south-facing slopes of the Smoky, Wapiti and Peace Rivers with subxeric moisture regimes and medium nutrient regimes the Western porcupine grass-Sedge/Fringed sage and Northern wheatgrass/Fringed sage community types are common (Figure 1). The Purple oatgrass-Sedge-California oatgrass community type is found on more upland sites with mesic moisture and medium nutrient regimes. Wilkinson and Johnston (1983) felt these grasslands to be the climax community type on Solonetzic soils. Indeed, Adams (1981) found the Western porcupine grass-Sedge dominated community on the Peace River slopes to be associated with Dark Gray Solods and Solonetzic Gray Luvisols. These grasslands provide important forage locally for both wildlife and domestic livestock. The grasslands of the south-facing river slopes are important spring forage sources because of early spring green-up.

On coarse textured, sandy soil, with submesic moisture and poor nutrient regimes which lack tree cover are found the Plains wormwood/Sedge and Saskatoon/Bearberry/Northern ricegrass community types. These community types are usually found in association with Jack pine dominated community types.

Wetter (subhydric/rich) sites are associated with sedge and marsh reedgrass dominated meadows. Sedge species are usually associated with the areas of free standing water and marsh reedgrass dominates the drier edges. Willow will invade into these meadows to form the Willow/Sedge and Willow/Marsh reedgrass community types.

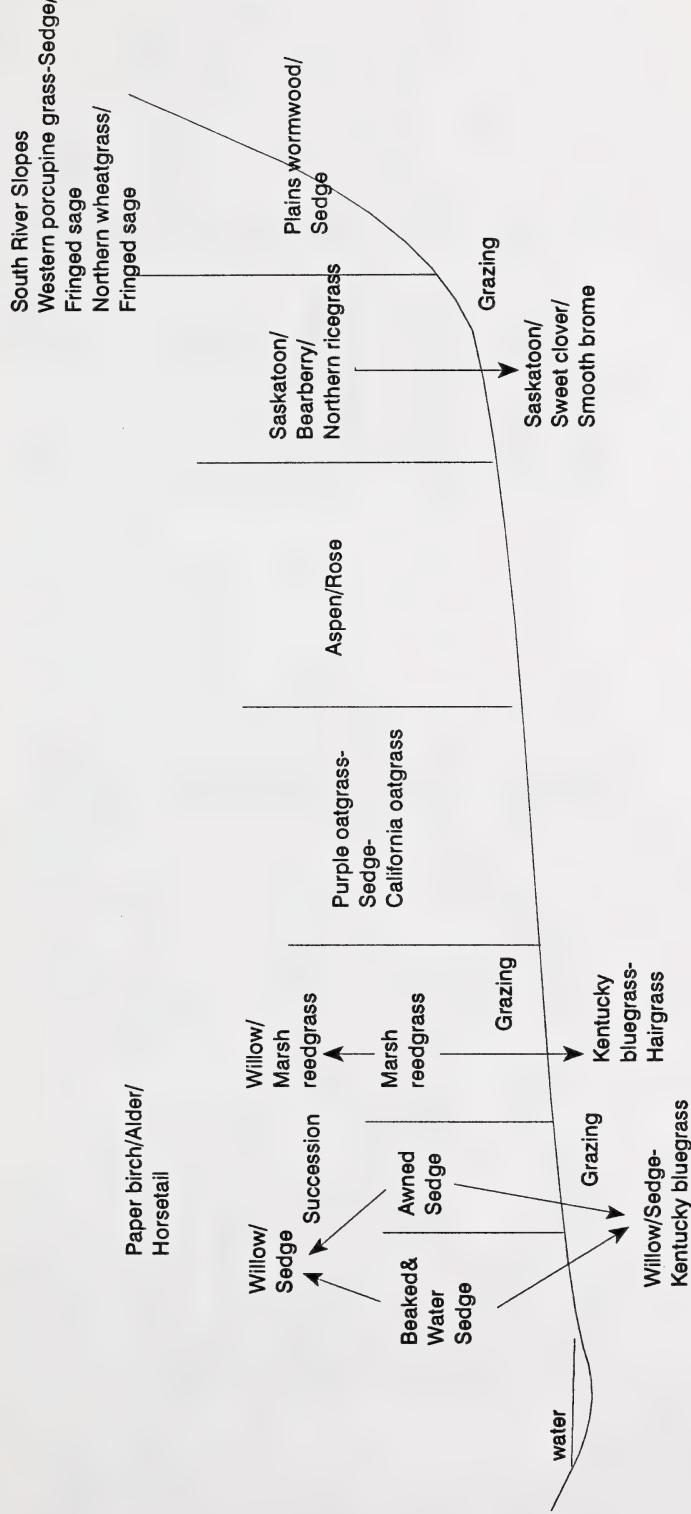

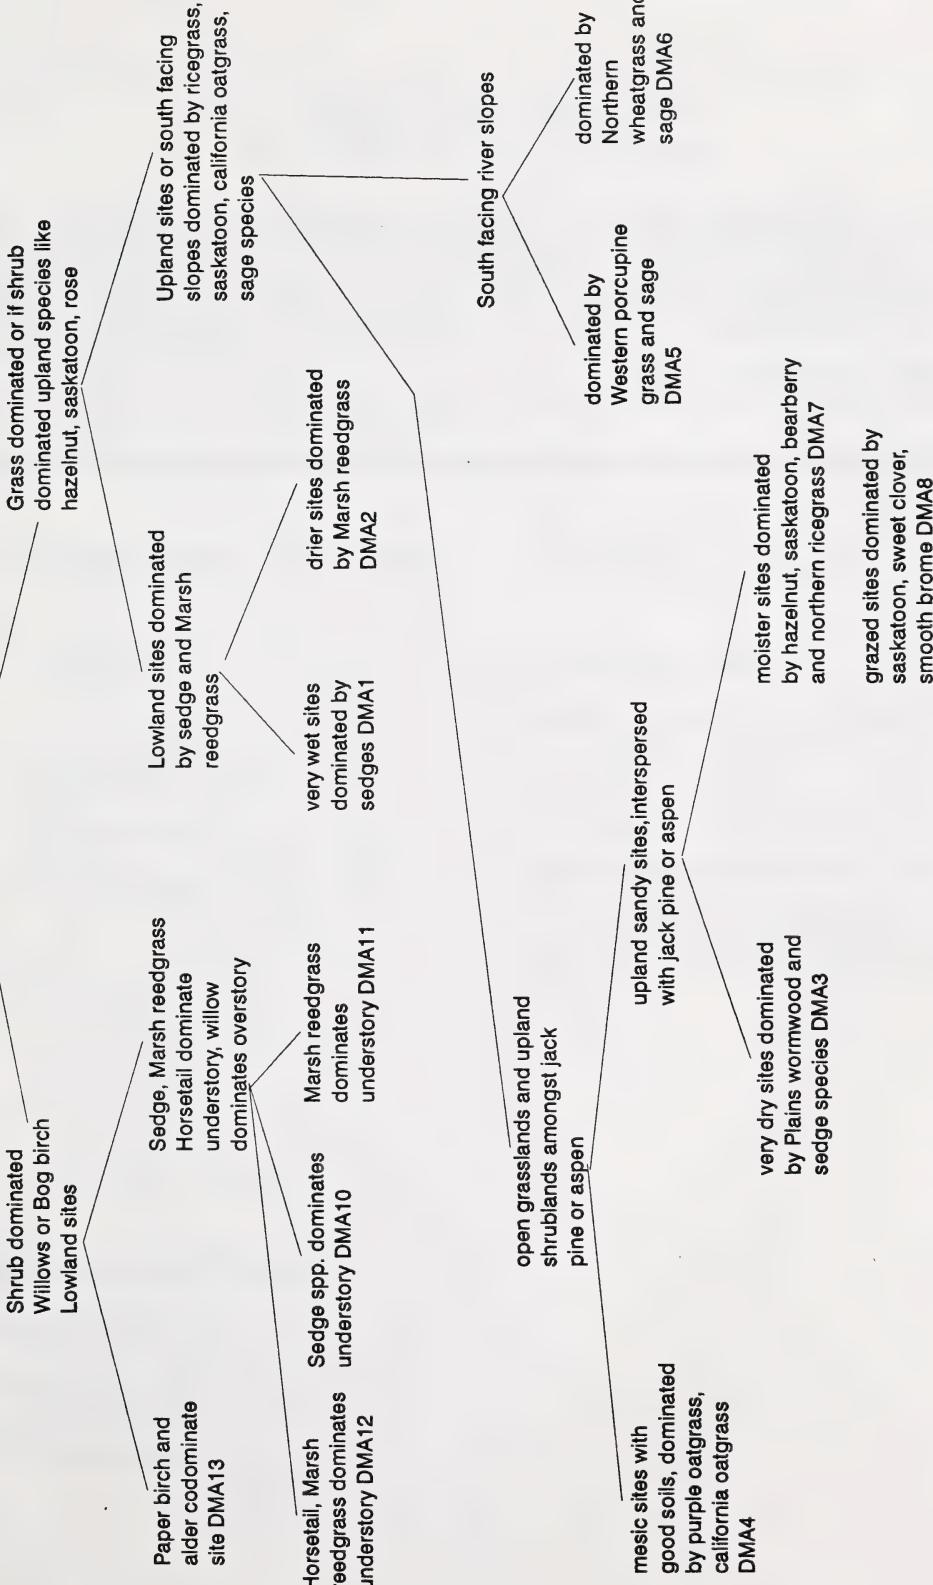

Figure 1. Ecology of the native grass and shrublands in the landscape of the Dry Mixedwood subregion.

Dry Mixedwood Grass and Shrublands

Key to native grass and shrublands in the Dry Mixedwood subregion

DMA1. Sedge meadows

(Carex aquatilis, C. rostrata, C. atherodes)

n=3 This wetland community type is found near fresh water. The sedge meadow is a poorly drained community. As one moves to the drier edges marsh reedgrass becomes predominant. Willows will invade into both the sedge and marsh reedgrass dominated meadows. The sedge meadow community is very productive, but the high water table, particularly in the spring when the sedge species are most palatable, restricts livestock movement. One study done in the Yukon found that crude protein on these meadows declined from a high of 10% in May to less than 5% in September (Bailey et al. 1992).

Beaked sedge found in abundance in this community is usually associated with nitrogen rich conditions and moving water (Brierly et al. 1985). Water sedge is often found in abundance in this community type and is associated with calcium rich stagnant water (MacKinnon et al. 1992).

DMA2. Marsh reedgrass meadow

(*Calamagrostis canadensis*)

n=1 This community is found on the edges of sedge meadows and moist draws where the water table is lower. The lower water table makes this community accessible for most of the grazing season. Willow will invade onto these sites to form the Willow/Marsh reedgrass community type. Increased grazing pressure on these sites will cause marsh reedgrass to decline and their will be an invasion of Kentucky bluegrass and dandelion. These sites are highly productive for domestic livestock and should be rated as primary range.

DMA3. Plains wormwood/Sedge

(Artemisia campestris/Carex spp.)

n=1 This community type is found on coarse textured, sandy soils. It is generally found on hilltops and south-facing slopes in openings among Jack pine on the uplands and black spruce in the lowlands. This community type was also described on similar site conditions in the Central Mixedwood subregion. This community would be considered either secondary or non-use range for domestic livestock because of the low forage production and fragile nature of the community.

DMA4. Purple oatgrass-Sedge-California oatgrass

(Schizachne purpurascens-Carex spp.-Danthonia californica)

n=4 This community appears to be characteristic of dry grassy meadows on dark colored Solonetzic soils and gentle to level areas throughout the Dry Mixedwood subregion. Wilkinson and Johnson (1982), found there was a close correlation between large tracts of prairie vegetation and the distribution of solonetzic soils in the Peace River district of Alberta. They specifically described Western porcupine grass-Sedge/Fringed sage community on steep south-facing slopes and a Sedge-California oatgrass-Western porcupine grass on more gentle slopes. They felt the solonetzic soils supported grasslands and not forests because of their unfavourable ratios of Ca and Na, hard, columnar B-horizon, and relatively impermeable clay pan close to the surface. This community type appears to more similar to their Sedge-California oatgrass-Western porcupine grass community type. It is likely the heavy grazing pressure of the described sites favours the growth of purple oatgrass over Western porcupine grass on these sites.

This community type would be rated as primary range. Indeed many of the sites described were old homestead sites.

DMA5. Western porcupine grass-Sedge/Fringed sage (*Stipa curtiseta*-*Carex spp.*/*Artemisia frigida*)

n=2 This community type is found on steep, south-facing slopes along the banks of the Peace, Smoky and Wapiti rivers throughout the Dry Mixedwood subregion. Wilkinson and Johnson (1982), found there was a close correlation between large tracts of prairie vegetation and the distribution of solonetzic soils in the Peace River district of Alberta. They specifically described Western porcupine grass-Sedge/Fringed sage community on steep south -facing slopes and a Sedge-California oatgrass-Western porcupine grass on more gentle slopes. They felt the solonetzic soils supported grasslands and not forests because of their unfavourable ratios of Ca and Na, hard, columnar B-horizon, and relatively impermeable clay pan close to the surface. Adams (1981), found this community type as being a major source of spring forage for livestock in the Peace River area. He found that with increased grazing pressure sedge, junegrass, northern and western wheatgrass would increase as western porcupine grass declines. Often this community type is on steep enough slopes to be considered non-use for domestic livestock.

DMA6. Northern wheatgrass/Fringed sage (*Agropyron dasystachyum*/*Artemisia frigida*)

n=1 This community type is found on steep, south-facing slopes along the banks of the Peace, Smoky and Wapiti rivers throughout the Dry Mixedwood subregion. Adams (1981), felt this community type would form when the Western porcupine grass community was heavily to moderately grazed, but this community type was described in an area that had little grazing pressure. This community was located on a much steeper slope (90% vs 35%) than the previously described Western porcupine grass community type. It is likely that the drier site conditions and shallower soils favour the growth of northern wheatgrass over Western porcupine grass. This community type is located on a steep enough slope to be considered non-use for domestic livestock.

DMA7. Saskatoon/Bearberry/Indian ricegrass

(Amelanchier alnifolia/Arctostaphylos uva-ursi/Oryzopsis pungens)

n=1 This community represents small grassy openings within jack pine forests. Jack pine stands are associated with rapidly drained, acidic soils and poor nutrient status due to the coarse-textured eolian and fluvial parent material (Beckingham and Archibald 1996). It is likely these grassy openings are even drier, which favours the growth of shrubs. Forage productivity on these sites is only moderate averaging only 677 kg/ha. These sites are also heavily utilized by wildlife. As a result caution should be used when managing these sites for domestic livestock grazing to prevent overutilization.

DMA8. Saskatoon/Sweet clover/Smooth brome

(Amelanchier alnifolia/Meliolatus officinalis/Bromus inermis)

n=2 This community type appears to represent the Saskatoon/Bearberry/Northern ricegrass community type which has undergone disturbance by livestock. Sweet clover and smooth brome are both weedy species and occur essentially where roads and settlement occurs. Sweet clover is well adapted to growing on roadsides and in waste places. Therefore, it is well suited to growing in the poor nutrient soils of the Saskatoon/Bearberry/Northern ricegrass community type. Unfortunately, forage production was not done for this community type, but sweet clover and brome can be very productive if grazed before they become overmature.

DRY MIXEDWOOD SUBREGION

TAME FORAGE COMMUNITIES

Photo 3. Typical Range improvement clearing in the Dry Mixedwood subregion

DM - TAME FORAGE COMMUNITIES

(Cleared areas that have been broken and seeded to tame forage)

Throughout the Dry mixedwood subregion there are sites that have been deforested, broken, and seeded to tame forage. Usually these areas are mesic and moderately well to well drained with good nutrient levels. Because most of these tame forage stands are established on similar sites, the most influential factors affecting plant species composition are stand establishment and grazing regime.

Stand establishment is important because it determines what the initial plant species composition is going to be. Seed bed preparation and the type of seed sown are the two most important factors influencing stand establishment. Seed bed preparation is important because it helps to determine how well the sown seed germinates and establishes. If the seed bed is not well prepared the tame forage stand may establish poorly and native species can become a dominant component of the plant community. If the seed bed is well prepared, the community type that establishes will depend on the type of seed sown. If a mixture of Creeping Red Fescue, Timothy, and Alsike Clover is sown into the area a Creeping Red Fescue/ Alsike Clover community type will become established. Whereas, if a mixture of Smooth Brome Grass, Timothy, Creeping Red Fescue, and Red Clover is sown, a Smooth Brome/ Red Clover community type will become established.

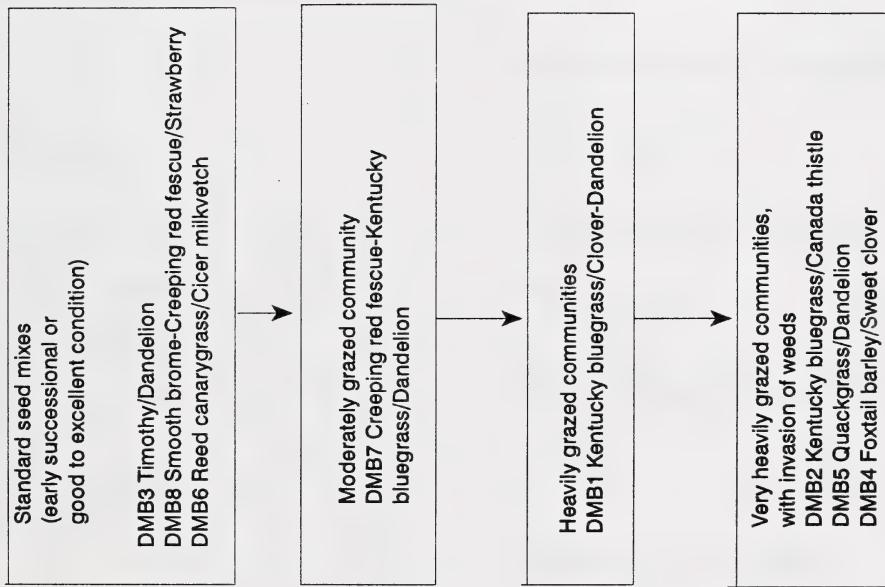

After the stand is established, the grazing regime applied to the stand will determine the plant species composition. Generally, a light to moderate amount of grazing allows the stand to maintain itself while sustained heavy grazing causes the stand to degrade. Damage to a stand due to over grazing occurs more readily while the stand is establishing than it does when the stand is established. This is because the forage plants in an establishing stand have not had time to develop energy reserves in their roots, and are therefore, more susceptible to grazing induced damage.

Well distributed light to moderate grazing will normally maintain a forage stand similar to what was seeded on the site. These stands are generally the most productive and provide the best grazing opportunities for livestock. They are normally considered to be in good to excellent range condition. Non use or very light grazing often results in the stand becoming dominated by the forage species that is most competitive under an ungrazed situation. Plant community changes which occur under heavy grazing are dependent on the grazing history (level of use, season of use and duration of the grazing regime). Overgrazed community types develop over a long period of repeated overgrazing. If weedy species such as Tall Buttercup, become established on overgrazed sites, they can quickly become a dominant species.

Table 3. Tame forage communities of the Dry Mixedwood subregion

Tame grass plant communities

Key to tame forage communities in the Dry Mixedwood subregion

DMB1. Kentucky bluegrass/Clover-Dandelion

(Poa pratensis/ Trifolium spp.-Taraxacum officinale)

n=7 This community type has had a history of being grazed heavily throughout the growing season. Heavy grazing throughout the growing season, allows kentucky bluegrass, clover, and dandelion to out-compete all of the other vegetation. This community occurs on tame pastures or native rangeland that has been over grazed. It is considered to be in poor condition because forage production and nutritional value have been degraded

DMB2. Kentucky bluegrass/Canada thistle

(Poa pratensis/Cirsium arvense)

n=1 This community type represents a native Marsh reedgrass community that has been heavily grazed for a prolonged period of time. The heavy grazing pressure has eliminated the native species cover and has allowed Kentucky bluegrass, dandelion and Canada thistle to invade onto the site. Canada thistle is unpalatable to livestock and restricts their movement throughout the field. If left untreated it will dominate the site and the field will become unuseable. Mowing or spraying with herbicide will help to control Canada thistle.

DMB3. Timothy/Dandelion

(Phleum pratense / Taraxacum officinale)

n=3 This community type develops on sites that were seeded with a timothy, smooth brome, creeping red fescue, clover mixture. Timothy establishes much quicker than creeping red fescue or smooth brome on pastures that have been recently seeded. Eventually creeping red fescue and smooth brome will outcompete timothy and this community will likely become dominated by creeping red fescue and smooth brome. Timothy provides excellent forage for domestic livestock, especially if timothy is kept in the vegetative state by mowing or grazing.

DMB4. Foxtail barley/Sweet clover (*Hordeum jubatum/Meliolatus officinalis*)

n=1 This community was found in a depressional area on a river flood plain in a field that appeared to have been cultivated. It is likely the cultivation process allowed foxtail barley to invade onto the site. Foxtail barley is also well adapted to growing on saline soils (Bailey et al. 1992). It is likely that the soils of this site are slightly saline. This community type would be considered non-use because the principle forage species foxtail barley is generally unpalatable to livestock. Foxtail barley can also cause injury to livestock. The sharp seeds and awns may work their way into tongues, gums, eyes, noses or skins of animals.

DMB5. Quackgrass/Dandelion

(Agropyron repens/Taraxacum officinale)

n=1 This community type was described next to an old homestead. Quackgrass is a rhizomatous, introduced species that has become well established in the settled portions of the province as a vigorous, persistent weed. If kept in the vegetative state it can provide good productive forage for domestic livestock. Unfortunately, once this species has established onto cropland it is very difficult and expensive to control.

DMB6. Reed canary grass/Cicer milkvetch

(*Phalaris arundinacea/Astragalus cicer*)

n=1 This community type represents pipelines that have been seeded with reed canary grass and cicer milkvetch. Reed canary grass establishes quickly in wet places that have been disturbed. Care should be taken when seeding reed canary grass. It appears that the commercial cultivars can be very invasive (Invasive plants of natural habitats 1992). In areas that have supported reed canary grass monocultures for extended periods many have seed banks devoid of other species. Cicer milkvetch is also well adapted to growing on moist soils, but this species is also invasive. Plants of cicer milkvetch were found growing off the pipeline under aspen. When seeding disturbed lands thought must be given to the compatibility of the tame species to the surrounding environment. The two dominant species of this community type appear to be invasive and probably should not have been seeded.

DMB8. Smooth brome-Creeping red fescue/Strawberry

(Bromus inermis-Festuca rubra/Fragaria virginiana)

n=1 This community type occurs on cleared pastures that were seeded with a smooth brome, creeping red fescue-clover mix. With a moderate grazing regime, smooth brome grass is the most competitive forage plant seeded into this site. It out-competes timothy because it is strongly rhizomatous and is able to fill in the gaps between plants allowing it to shade out the timothy reducing its prominence in the stand. Smooth brome grass also out-competes creeping red fescue because it establishes faster.

DRY MIXEDWOOD SUBREGION

DECIDUOUS FOREST COMMUNITY TYPES

Photo 4. Aw/Rose/Tall forb community type in the Dry Mixedwood subregion

DM - DECIDUOUS FOREST COMMUNITIES

All of the deciduous stands sampled in the Dry Mixedwood subregion were dominated by aspen and had a significant rose understory. In both Brierley et al. (1985) and Beckingham's (1993) deciduous classifications in the same subregion rose was the dominant or codominant understory shrub species in nearly every aspen-dominated community type. In Beckingham's classification rose was present in 205 of the 209 aspen-dominated stands. Rose is well adapted to a wide variety of site conditions with a moderate supply of nutrients. The moisture regime can vary from submesic to subhygric and the sites can be well to imperfectly drained.

It appears the secondary forb and shrub species in association with rose characterize the ecological conditions of aspen forest types in the Dry Mixedwood subregion. Indeed, many of the deciduous types in Beckingham's classification were based on the secondary shrub species.

In the Dry Mixedwood classification 9 community types were described in the Grande Prairie and Peace River area (Debolt, Dunvegan, Falher, Smoky, Grimshaw, Manning, High Level and Boyer Plains ecodistricts)(Strong and Thompson 1995). The Aspen/Bearberry-Rose type is found on well-drained, sandy sites in association with jack pine stands. The Aspen/Alder-Rose type is found on moist, moderately drained sites at higher elevations and the Aspen/Rose(Aw/Rose/Tall forb, Aw/Rose/Low forb, Aw/Rose-Hazelnut, Aw/Buffaloberry-Rose and Aw/Saskatoon-Rose) site types are moderately well-drained, with mesic moisture and mesotrophic nutrient regimes. Beckingham (1993), felt the Aspen/Buffaloberry type occurred on somewhat nutrient-poor soils. The three stands in this classification were also found at higher elevations (>650 m). The Aspen/Rose/Tall and Low forb community types occupy similar site conditions. The difference between these two types may be related to grazing pressure. The Aspen/Rose/Low forb type has a low total cover of forbs (48%), whereas the Aspen/Rose/Tall forb type has a high total cover of forbs (81%). The increased grazing pressure in the Aspen/Rose/Low forb type may have caused a reduction in forb cover. The Aspen/Rose-Hazelnut type is found on mesic, well-drained sites and appears to be the reference deciduous type for this subregion, particularly in the more eastern ecodistricts. The Aspen/Horsetail type was found on one moist poorly drained site adjacent to some willow shrublands.

One balsam poplar-dominated community was described in the western ecodistricts. This community was very typical of forests situated along the flood plains of rivers.

The hazelnut-dominated community types were very common within the eastern ecodistricts in the southern part of the subregion (St. Paul, Bonnyville, Smoky Lake). The presence of hazelnut appears to be indicative of warmer sites (Beckingham 1993) and have some fire history (Downing and Karpuk 1992). The Aw/Hazelnut-Rose/Wild sarsaparilla was slightly moister and appears to have a higher nutrient regime than the Aw/Hazelnut-Rose/Peavine community type. The Aw/Rose-Blueberry community type is typical of sandy, well-drained sites throughout the Dry Mixedwood subregion. This community type is very similar to the Aw/Blueberry-Rose community type described in the Central Mixedwood subregion. The Aw/Rose-Low-bush cranberry community type was described on the border between the Central and Dry Mixedwood subregions. It resembles the modal Aw/Rose-dominated community described in the Central Mixedwood subregion. The sequence of community types in the landscape of the eastern ecodistricts is outlined in figure 2.

Aw - Aspen

Deciduous community types (Eastern ecodistricts)

WESTERN ECODISTRICTS (GRANDE PRAIRIE, PEACE RIVER)

DMC1. Aw/Rose/Bearberry
(Populus tremuloides/Rosa acicularis/Arctostaphylos uva-ursi)

n=3 This community type is found on dry, well-drained, sandy sites interspersed with stands of jack pine and is part of the blueberry ecosite outlined by Beckingham and Archibald (1996). The canopy cover of aspen is open allowing for easy access by livestock, but the dry site conditions and poorer nutrient status limit the amount of regrowth after grazing. If this community type is managed for one rotation a year, it can contribute significantly to the overall carrying capacity of a lease. This community type would be considered to be primary range for domestic livestock.

DMC2. Aw/Rose/Tall forb

(Populus tremuloides/Rosa acicularis/Tall forbs)

n=8 This community type is part of the low bush cranberry ecosite outlined by Beckingham and Archibald (1996). This community type is also very similar to the Aspen/Rose/Low forb community type, but the cover of forbs is much higher. This appears to be related to the grazing pressure. The higher the grazing pressure on the Aw/Rose/Tall forb community type appears to cause a reduction in the cover of tall growing forbs (wild sarsparilla, fireweed, peavine, showy aster) and favours the growth of low growing forbs (bunchberry, dewberry, wintergreen, strawberry). This community type is providing a moderate amount of forage for domestic livestock and would be considered primary range on a forested disposition.

DMC4. Aw/Rose-Hazelnut

(Populus tremuloides/Rosa acicularis-Corylus cornuta)

n=6 Beaked hazelnut is a common component of many of the deciduous stands in both the western and eastern ecodistricts of the Dry Mixedwood subregion. The presence of hazelnut appears to be indicative of warmer sites and have some fire history (Downing and Karpuk 1992). The total forage productivity of this community type is only moderate, but the majority of the production is coming from hazelnut, which is largely unpalatable to livestock at proper stocking levels. The high cover of hazelnut also restricts access to livestock, limiting the forage availability. This community type would be rated as secondary range.

DMC5. Aw/Buffaloberry-Rose

(Populus tremuloides/ Shepherdia canadensis-Rosa acicularis)

n=3 This community type was found on mesic sites at higher elevations in the Saddle and Birch hills. Beckingham (1993) felt the Aw/Buffaloberry type was slightly drier and had a slightly poorer nutrient regime than the modal Aw/Rose community types. This type is providing a moderate amount of forage for domestic livestock, but the drier site conditions and poorer nutrient status will limit regrowth after grazing. Buffaloberry the predominant shrub species in this community type, is generally unpalatable to livestock.

DMC6. Aw/Alder/Mountain ricegrass

(Populus tremuloides/ Alnus crispa/Oryzopsis asperifolia)

n=1 This community type was described at a higher elevation (600 m) in the Dry Mixedwood subregion. Brierly et al. (1985) and Beckingham (1993) both described aspen-alder communities at higher elevations (>600m). It appears that the presence of alder may indicate a transition from the Dry Mixedwood into the Lower Foothills subregion.

This community type is providing a moderate amount of forage for domestic livestock, but the high cover of alder will limit access. Consequently, this community type should be rated as secondary range.

DMC7. Aw/Saskatoon-Rose

(Populus tremuloides/ Amelanchier alnifolia-Rosa acicularis)

n=1 This community type is found on mesic, well drained south facing slopes that overlook rivers and creeks. Generally, hazelnut, chokecherry, saskatoon and snowberry are indicative of the Dry Mixedwood subregion and are usually found associated with each other. When saskatoon predominates it usually occurs on south and west facing slopes. Saskatoon provides important browse for wild ungulates. Livestock also find saskatoon palatable and in areas where there is extensive cattle grazing this species can be heavily browsed.

DMC8. Pb/Red osier dogwood-Rose

(Populus balsamifera/Cornus stolonifera-Rosa acicularis)

n=1 This community type is typical of river floodplains throughout the Dry Mixedwood subregion. This community type tends to have a subhygric moisture and rich nutrient regime. Beckingham and Archibald (1996) found this community type on mid to lower slope topographic positions or near water courses where they receive nutrient-rich seepage or flood waters for a portion of the growing season. This community type is one of the most productive in the Dry Mixedwood subregion, but the high cover of shrubs limits access to livestock. The high cover of tall growing shrubs (alder, red osier dogwood) also limits the growth of low shrubs, forbs and grass the principle forage species for domestic livestock in deciduous forests. As a result, this community should be rated as secondary or non-use range.

DMC9. Aw/Horsetail

(*Populus tremuloides/Equisetum arvense*)

n=1 This community occupies lowland sites adjacent to black spruce and willow lowlands. It is very moist and nutrient-rich. Horsetail types in the other subregions also tend to be moister and richer than the modal Aw/Rose types. Past overgrazing pressure appears to have been heavy at this site resulting in an alteration of understory species composition and productivity. Overuse in the past has resulted in less species diversity and an abundance of the increaser plant horsetail.

DMC10. Deciduous cutblocks and unseeded clearings

(Populus tremuloides)

n=4 This community type represents deciduous cutblocks and clearings that have not been seeded to tame forage species. Marsh reedgrass and strawberry initially dominated these areas. As succession occurs an understory of aspen and rose predominate. As the tree cover increases the understory species structure and diversity declines. Initially these clearings are very productive for domestic livestock until the trees grow back and limit accessibility. Care should be taken when grazing these cutblocks that the trees are not damaged and there is sufficient regrowth to regenerate the cutblock.

EASTERN ECODISTRICTS (SMOKY LAKE, ST PAUL)

Photo 5. Aw/Hazelnut-Rose community is very common in the eastern ecodistricts of the Dry Mixedwood subregion.

DMC11. Aw/Rose-Low bush cranberry

(Populus tremuloides/Rosa acicularis-Viburnum edule)

n=11 This community type occurs mainly along the Dry Mixedwood and Central Mixedwood subregion boundary in east-central Alberta. Stands occur on moderately moist, moderately well-drained and medium-textured Orthic Gray Luvisols that have developed in slightly stony till deposits. Slopes are gentle with variable aspects. This type may be expected farther south in the east-central part of the subregion on sites that are cooler and moister than the average. Like other deciduous community types described in the Central Mixedwood, this community type produces a moderate amount of forage for domestic livestock and would be rated as secondary range.

DMC12. Aw/Rose-Blueberry

(Populus tremuloides/ Rosa acicularis-Vaccinium myrtilloides)

n=4 This community type is scattered throughout the Dry Mixedwood subregion on mainly dry, rapidly to well-drained sites. Sandy glaciofluvial veneers and blankets or rubble clays typically mantle fine-textured till deposits. Soil nutrient levels are judged to be poor (submesotrophic) relative to other vegetation types because soils are slightly to moderately acid and have sandy to stony textures in the upper soil horizons. These stands tend to be relatively open allowing for easy access by livestock, but the dry site conditions and poorer nutrient status limit the amount of regrowth after grazing. If this community type is managed for one rotation a year, it can contribute significantly to the overall carrying capacity of a lease.

DMC13. Aw/Beaked hazelnut-Rose/Wild peavine

(Populus tremuloides/Corylus cornuta-Rosa acicularis/Lathyrus ochroleucus)

n=13 This community occurs mainly in the south half of the Dry Mixedwood subregion in east-central Alberta. Typical sites are judged to be moderately well-drained and moderately moist. The trend toward warmer, drier conditions with more southerly locations in the Dry Mixedwood may explain the dominance of this type over the Aw/Beaked hazelnut-Rose/Wild sarsaparilla community type in this part of the subregion. The presence of high peavine cover appears to be indicative of a boreal-parkland climatic transition. The total forage production of this community type is moderate, but the majority of the production is coming from hazelnut, which is largely unpalatable to livestock at proper stocking levels. The high cover of hazelnut also restricts access to livestock and limits the forage availability. This community type would be rated as secondary range.

DMC15. Aw/Rose/Forb/Marsh reedgrass

(Populus tremuloides/Rosa acicularis/Forb/Calamagrostis canadensis)

n=25 This community type is the most common and widespread aspen forest type found in the Dry Mixedwood subregion of east-central Alberta. Typical parent materials are moderately well to imperfectly drained, fine-textured and gently sloping till deposits in which Orthic and Gleyed Gray Luvisols have developed. This type is difficult to distinguish from the Aw/Rose-Low bush cranberry type towards the northern limit of the subregion. In the latter type the major distinguishing characteristic is the infrequent occurrence of beaked hazelnut. This community type is fairly productive and produces a moderate amount of palatable forage for domestic livestock. Consequently, this community type would be rated as secondary range.

DRY MIXEDWOOD SUBREGION

CONIFEROUS AND MIXEDWOOD FOREST COMMUNITIES

Photo 6. Pj/Bearberry community type in the Dry Mixedwood subregion

DM-CONIFEROUS AND MIXEDWOOD FORESTS

The mixedwood and coniferous community types described in this guide represent four ecosites as described by Beckingham and Archibald (1996). On sites with subxeric moisture and poor nutrient regimes, coarse textured, sandy soils open stands of jack pine generally dominate (Pj/Alder, Pj/Bearberry). These community types commonly have a carpet of lichens covering the forest floor and a thin organic layer typically less than 5 cm thick (Beckingham and Archibald 1996).

On slightly moister sites with submesic moisture and medium nutrient regimes aspen grows in conjunction with jack pine to form the Pj-Aw/Bearberry community type. The soils of this community type continue to be coarse-textured but the moisture and nutrient conditions are more favourable to the growth of aspen.

The mesic/medium sites are generally dominated by white spruce (Sw/Buffaloberry/Bearberry, Sw/Moss) and mixedwood communities of aspen and spruce (Aw-Sw/Rose/Marsh reedgrass, Aw-Pb-Sw/Willow/Wild sarsparilla, Sw-Pb-Aw/Rose/Twinflower). These communities represent the reference ecosite for the Boreal Mixedwood subregion (Beckingham and Archibald 1996). Generally, these sites have moderately fine to fine-textured till or glaciolacustrine parent materials. Pioneer deciduous species (aspen, balsam poplar and birch) are replaced with white spruce and balsam fir as these sites develop successionaly. With succession shade tolerant plants take over the herbaceous layer as conifers dominate the canopy. These shade tolerant species are unproductive and often unpalatable for domestic livestock. Forage productivity declines from 2.3 ha/AUM in a deciduous community to 2.3-8.6 ha/AUM in a mixedwood community to less than 10 ha/AUM in a conifer community.

Black spruce and larch communites generally dominate on wetter sites with subhygric to subhydric moisture regimes and poor to medium nutrient regimes to form the Sb/Willow/Moss and Sb-Lt/Labrador tea/Moss community types. Larch is more tolerant of excessive moisture and is indicative of an enriched nutrient status, while black spruce is typical in areas of stagnating ground water with poor nutrient status (Hay et al. 1985). Generally, these community types are considered non-use for domestic livestock.

Beckingham and Archibald (1996), provide a good description on how the conifer and mixedwood community types are arranged in the landscape.

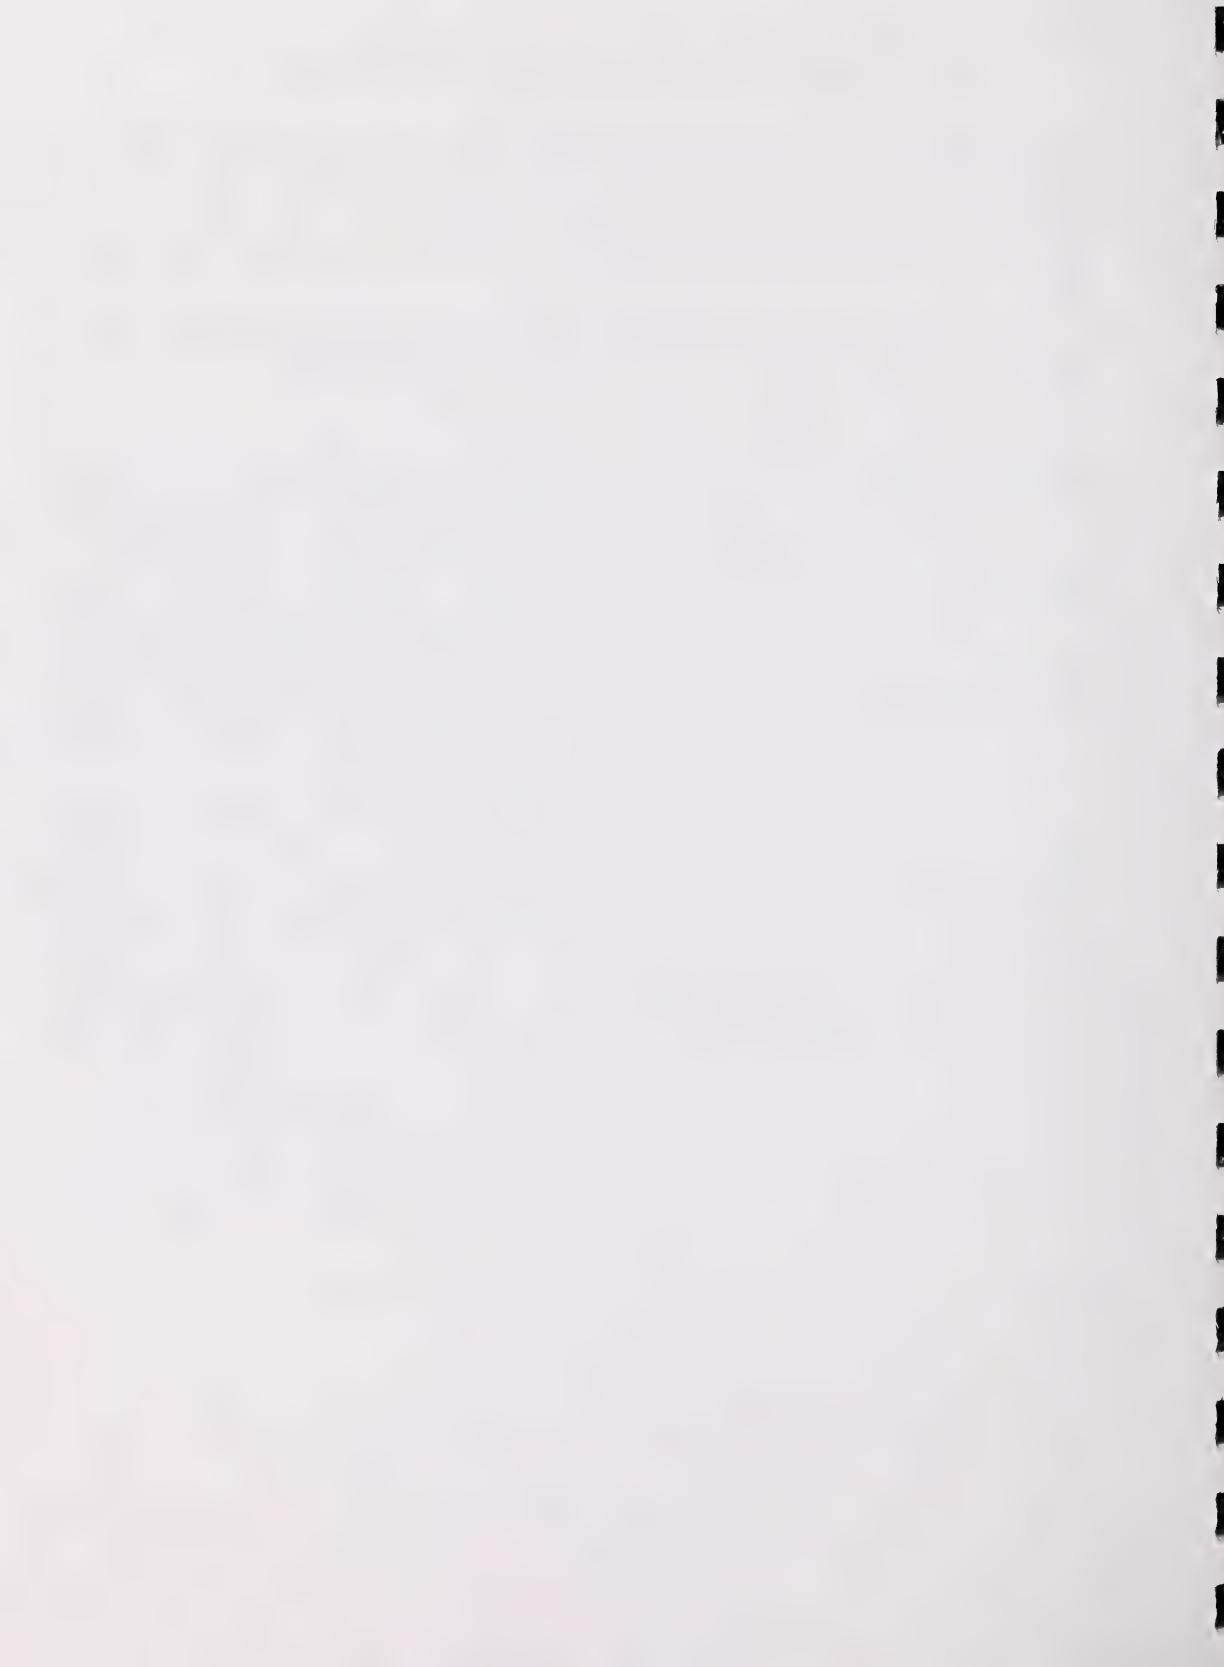

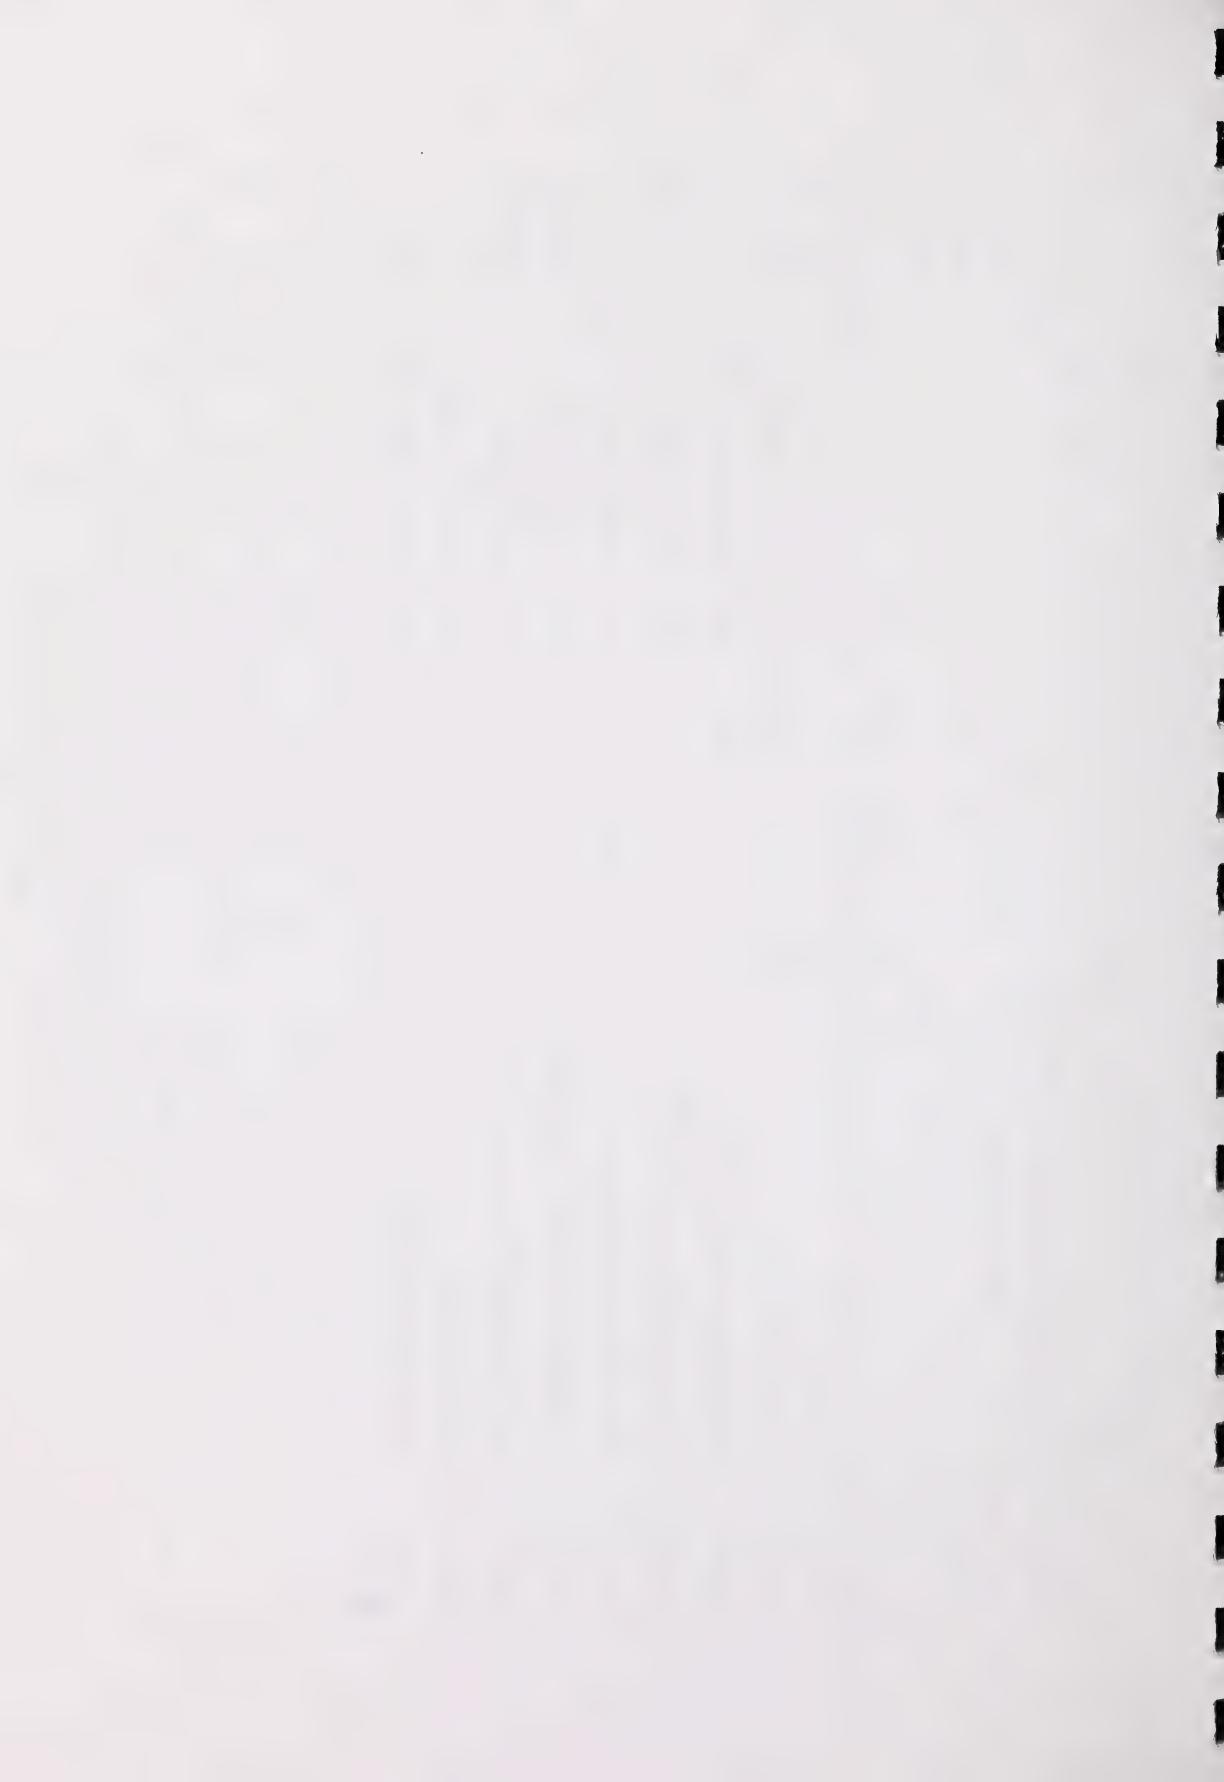

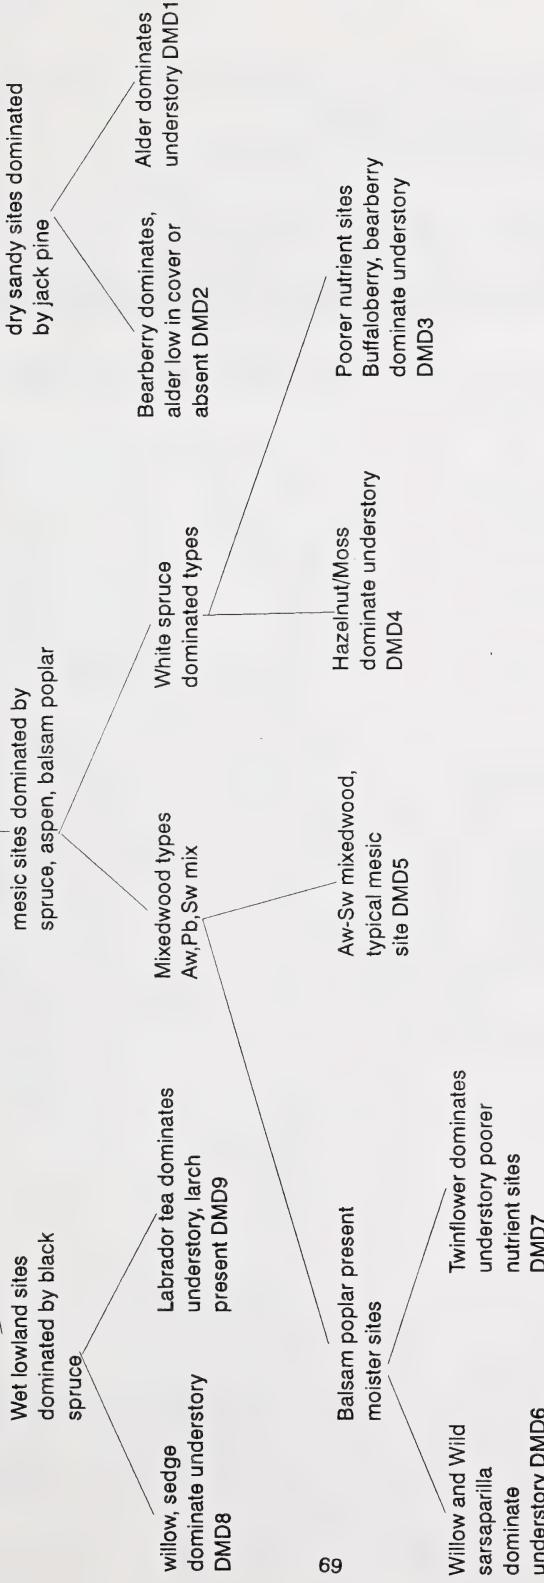

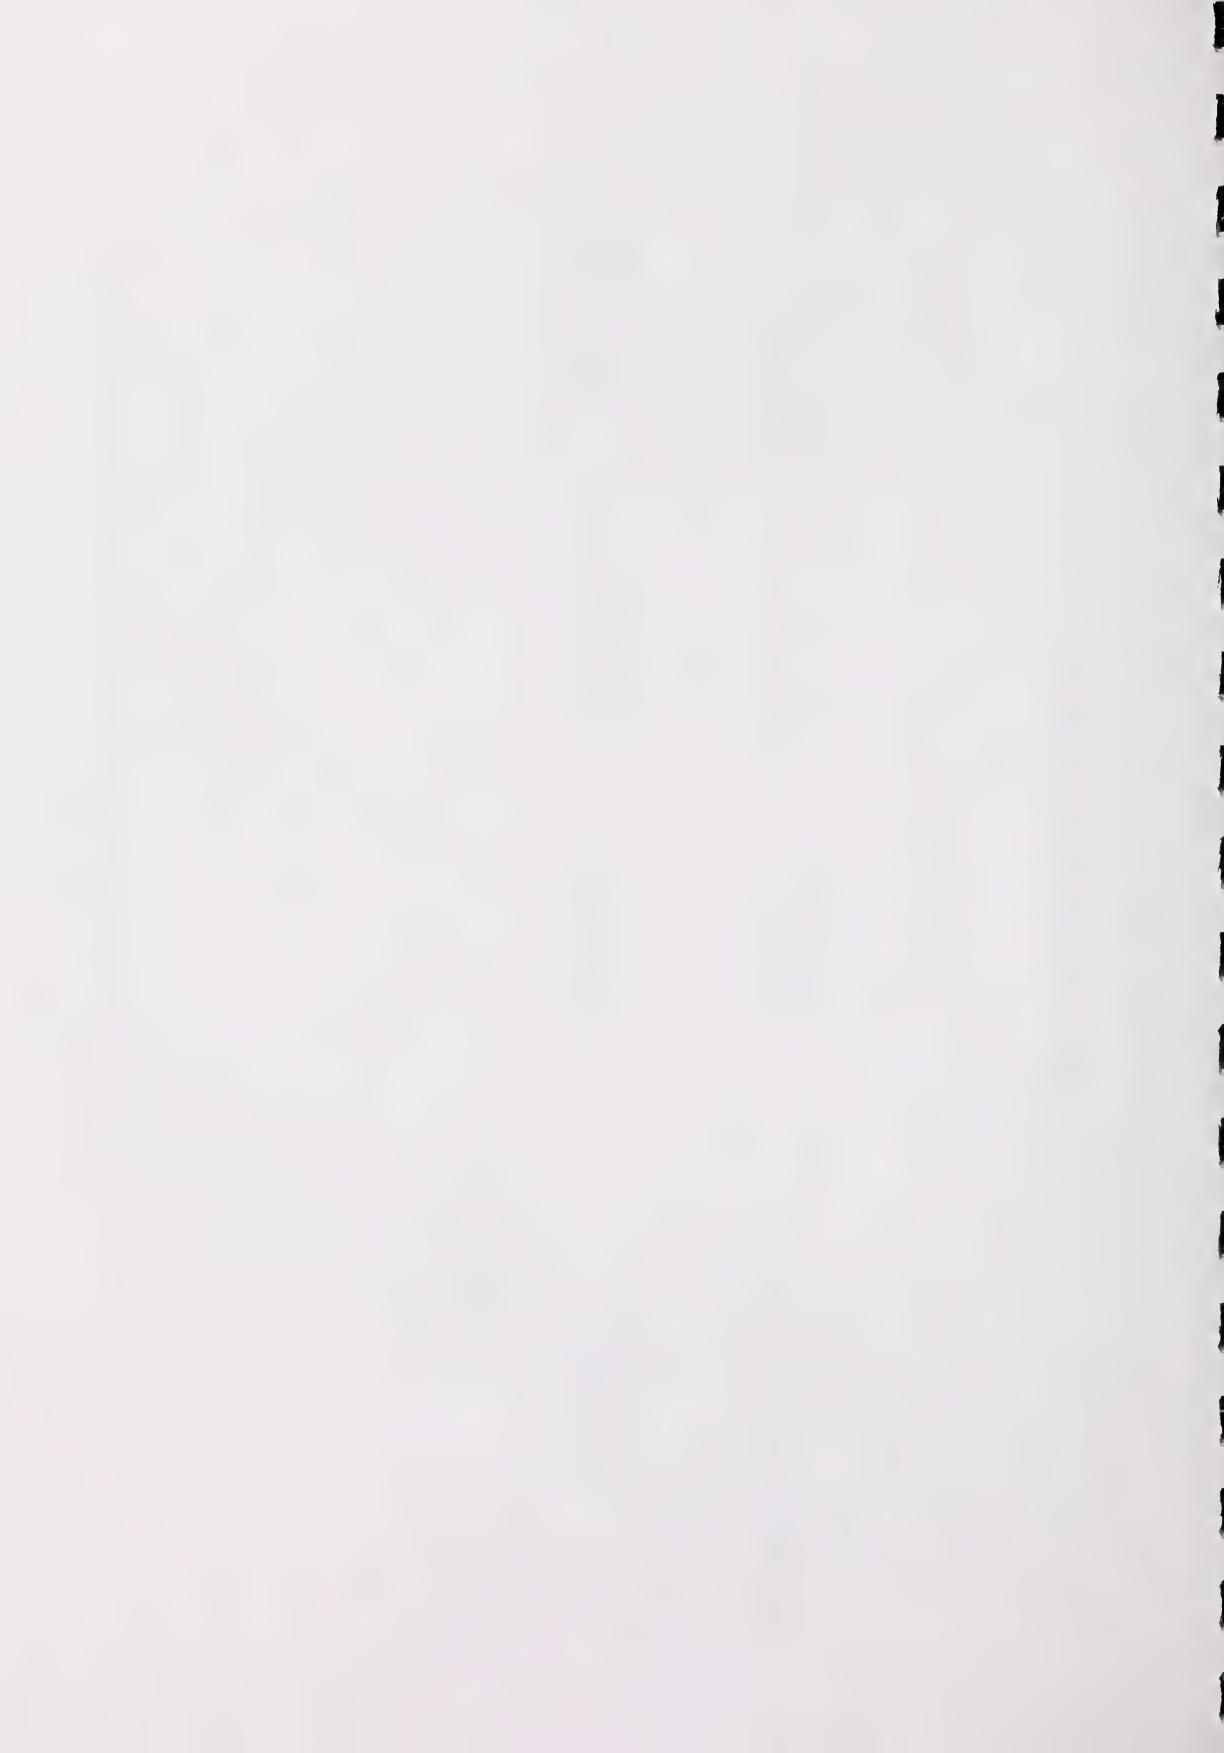

Table 5. Conifer and Mixedwood communities of the Dry Mixedwood subregion

Conifer and Mixedwood types Dry Mixedwood

DMD1. Pj/Alder

(Pinus banksiana/ Alnus crispa)

n=2 This community type is found on dry, rapidly drained, sandy soils with a poor nutrient status. Consequently, production is quite low. Cattle will utilize these areas due to the easy access, however overutilization will quickly deplete the area of forage. This community type would be rated as secondary or non-use range.

ENVIRONMENTAL VARIABLES

MOISTURE REGIME:

DMD2. Pj-Aw/Bearberry

(Pinus banksiana/Arctostaphylos uva-ursi)

n=4 This community represents a jack pine forest with a secondary canopy of aspen. It is very similar to the Pj/Alder community type, but it is found on slightly moister soils with better nutrient regimes. These conditions favour the growth of aspen. Like the previous community, cattle will utilize these area due to the easy access, however overutilization will quickly deplete the forage supply. This community type would be rated as secondary range and should be grazed on a single rotation per year.

DMD3. Sw/Buffaloberry/Bearberry

(Picea glauca/ Shepherdia canadensis/Arctostaphylos uva-ursi)

#1 This community type represents a very open spruce forest. It was found on a small, sandy hillcrest with a high water table. The site may have a high pH and be somewhat nutrient poor as indicated by the abundance of buffaloberry (Beckingham 1993). The majority of productivity is from buffaloberry which is unpalatable to livestock. Consequently, this community type would be considered non-use range.

NUTRIENT REGIME:

DMD4. Sw/Beaked hazelnut/Moss

(Picea glauca/Corylus cornuta/ Moss)

n=1 This is a mature white spruce forest which represents the climax or near climax vegetation for the area. The northerly aspect of this community type has probably protected the site from past disturbance by fires and allowed the community to undergo succession. The high canopy of spruce limits the light reaching the forest floor, limiting the growth of grasses and forbs. As a result, the forage productivity of this community type is very low. This community would be considered non-use.

CENTRAL MIXEDWOOD SUBREGION

GRASSLAND AND SHRUBLAND COMMUNITY TYPES

Photo 7. This picture represents the Sheep fescue/Plains wormwood community type. This community type is common on dry sandy hills throughout the Central Mixedwood subregion.

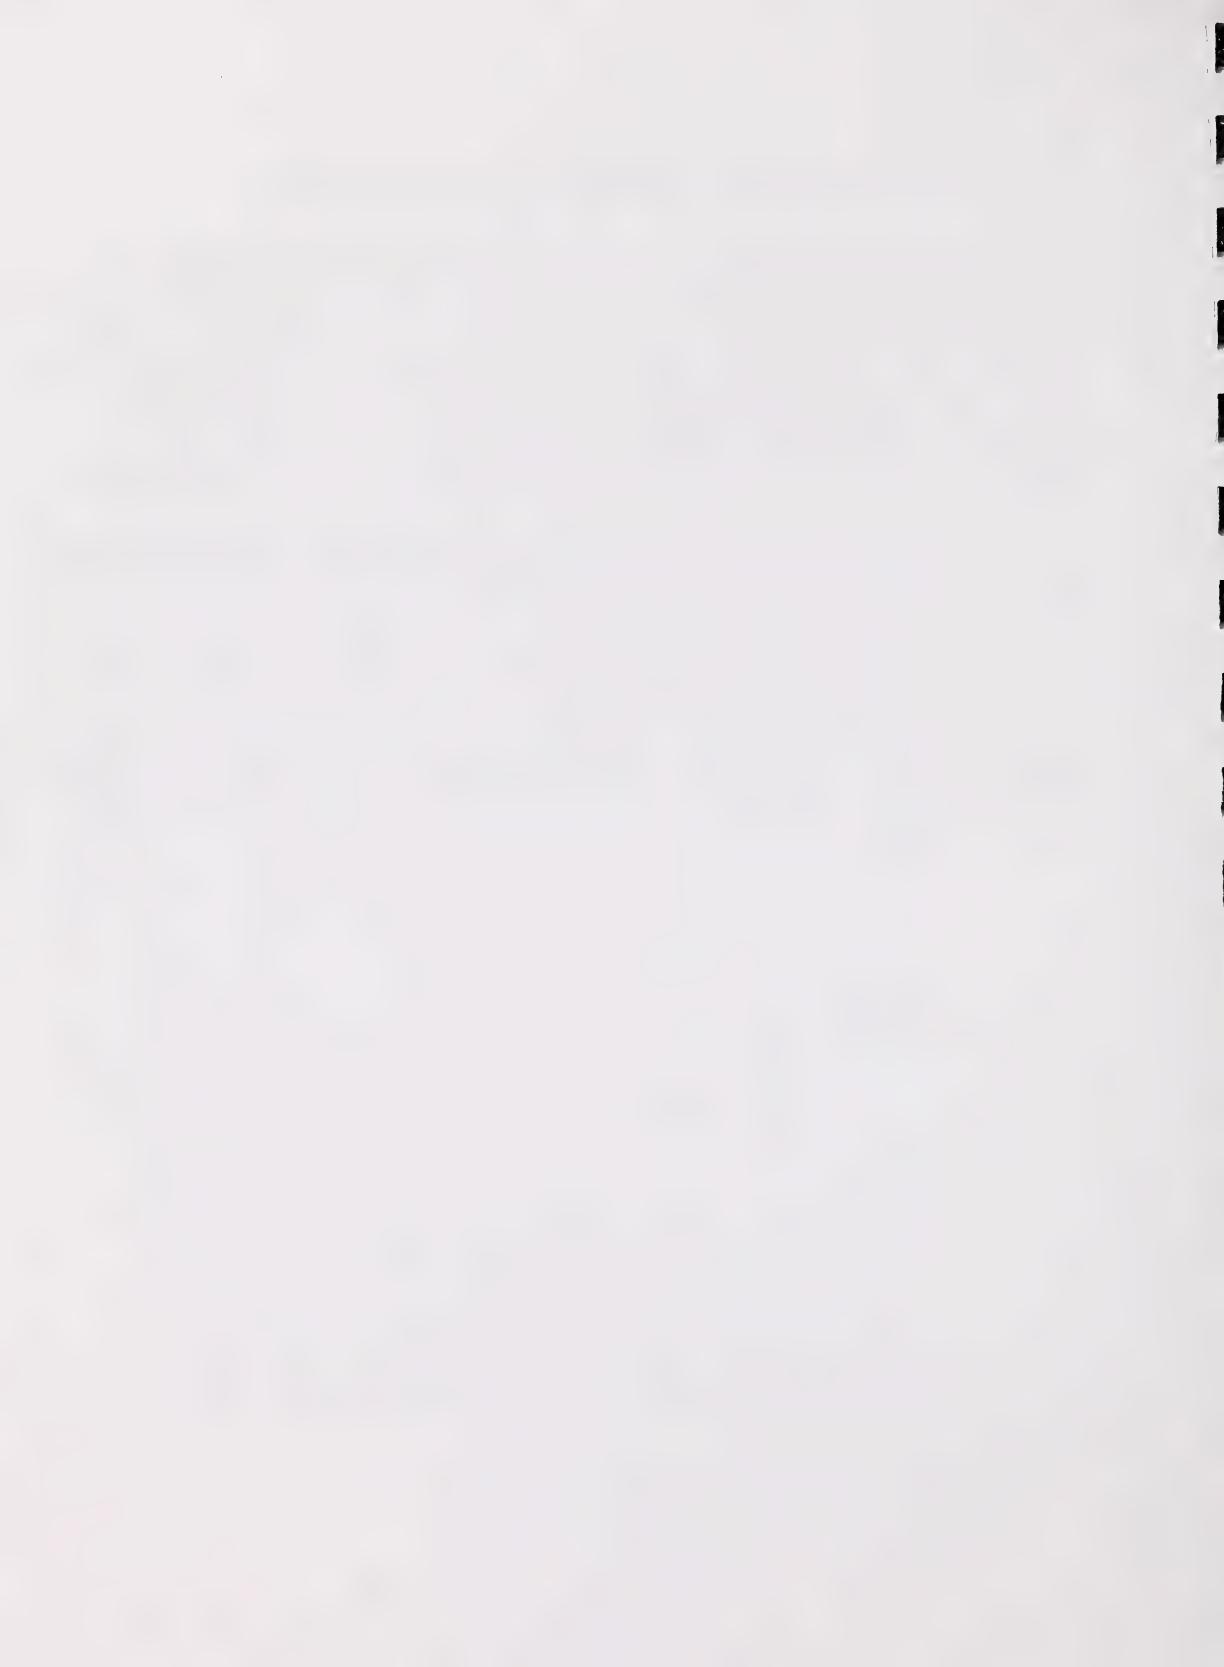

CM - NATIVE GRASS AND SHRUBLAND COMMUNITIES

Upland native grasslands are very rare in the Central Mixedwood subregion. The communities that have been described on coarse textured, sandy soil, with submesic moisture and poor nutrient regimes which lack tree cover are the Plains wormwood/Sheep fescue-Sedge community type. This community type is usually found in association with jack pine dominated community types. Heavy grazing of this community type leads to a Kentucky bluegrass-Sedge/Plains wormword dominated type. On level, gravelly, well-drained sites adjacent to streams and rivers a snowberry dominated community type is common. This community is extensively grazed by livestock to form the Snowberry/Kentucky bluegrass dominated type (Figure 3).

Wetter (subhydric/rich) sites are associated with sedge and marsh reedgrass dominated meadows. Sedge species are usually associated with the areas of free standing water and marsh reedgrass dominates the drier edges. Willow will invade into these meadows to form the Willow/Sedge and Willow/Marsh reedgrass community types. Under grazing pressure these community types tended to be invaded by dandelion, clover and Kentucky bluegrass to form the Willow/Sedge-Kentucky bluegrass community type.

Fire is an important part of the ecology to the Central Mixedwood subregion. There are a number of shrubland community types which have a strong fire origin. These include the Willow-Alder/Marsh reedgrass, Willow/Fireweed and Willow-Spruce/ Kentucky bluegrass dominated community types.

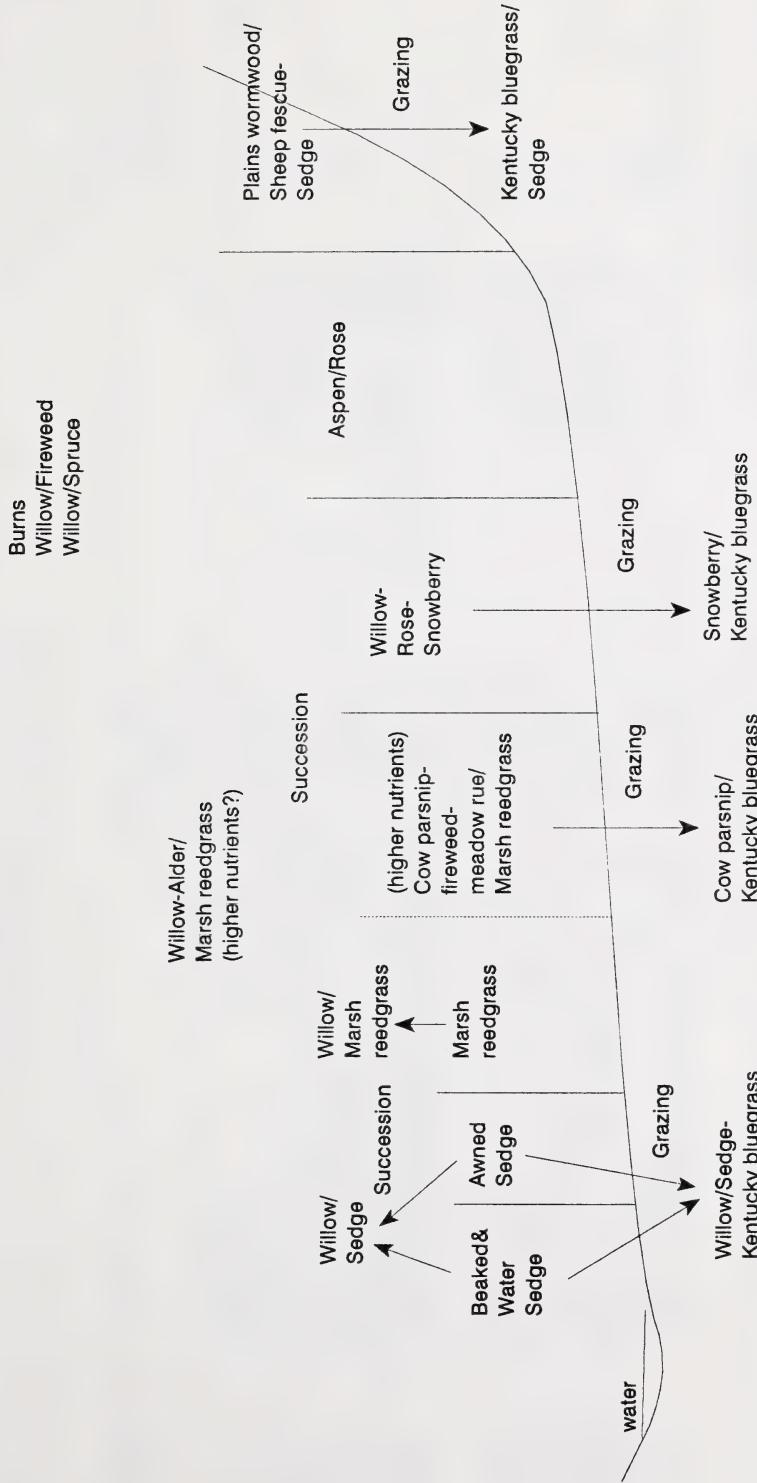

Figure 2. Ecology of the native grass and shrublands in the landscape of the Central Mixedwood subregion.

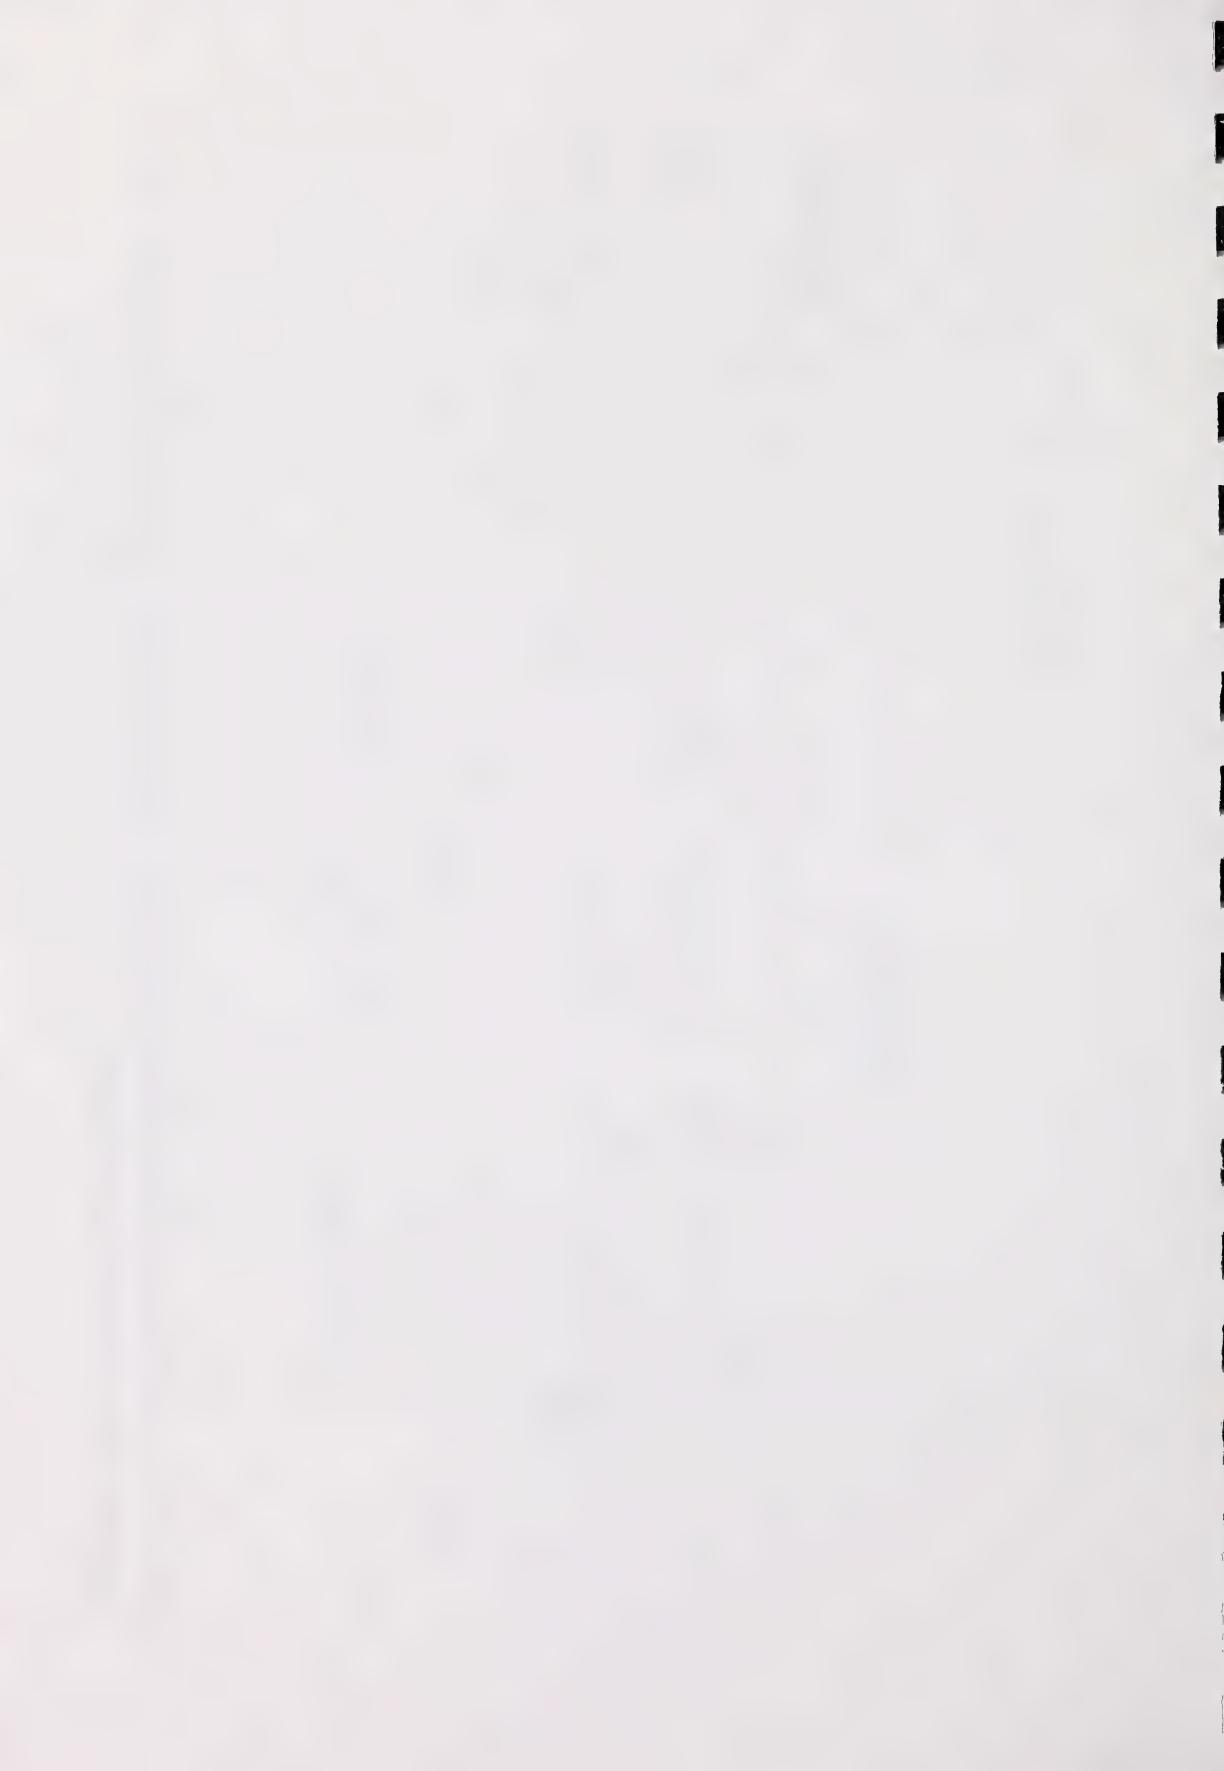

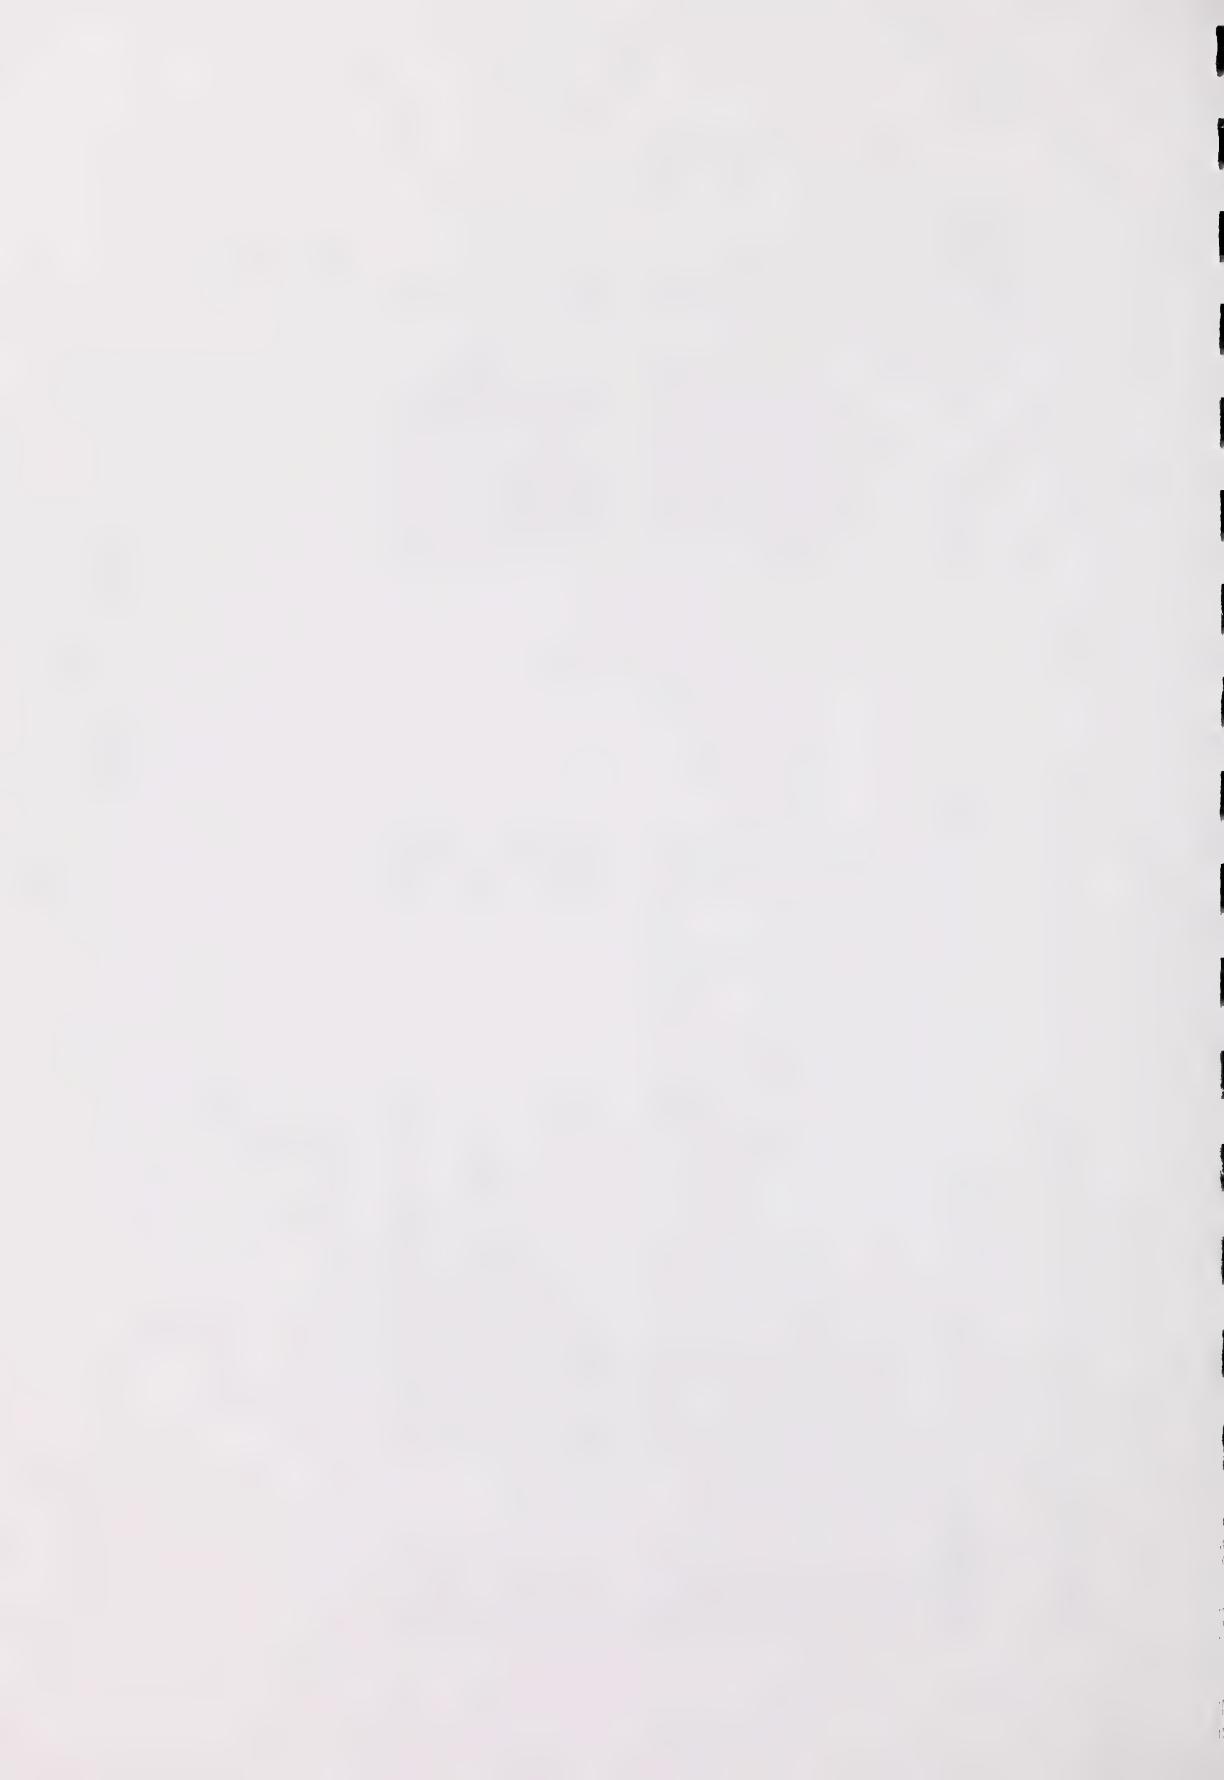

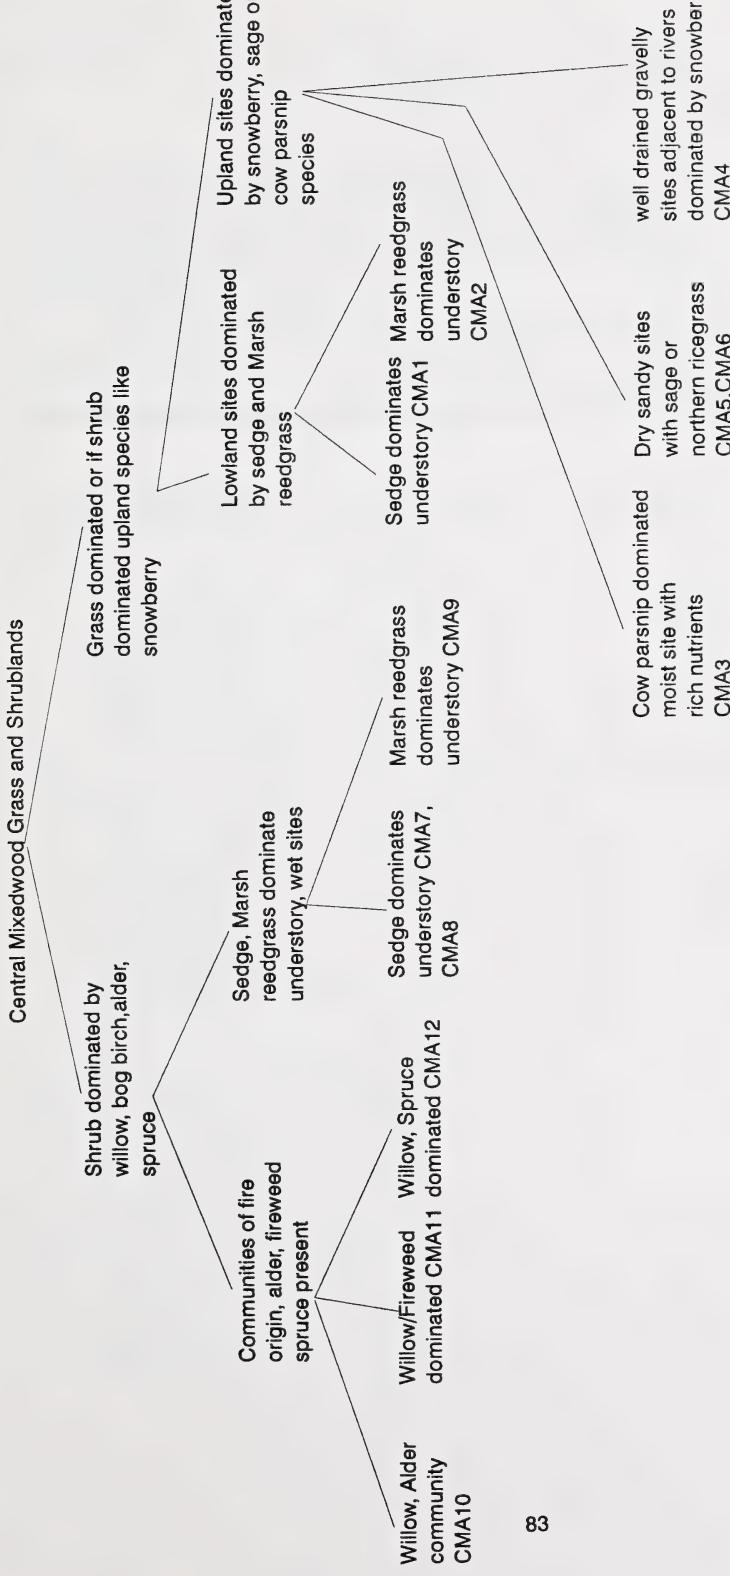

Table 6. Grass and shrub community types for the Central Mixedwood subregion

Community number	Community type	Total productivity (Kg/ha)	Ecosite	Carrying Capacity (Ha/AUM)

CMA11	Willow/Fireweed	1748	(mesic/medium)	0.5
CMA12	Willow-Spruce/Kentucky bluegrass	2524	(mesic/medium)	0.4

CMA1. Sedge meadows

(Carex aquatilis, C. rostrata, C. atherodes)

n=5 This wetland community type is found near fresh water. The sedge meadow is a poorly drained community. As one moves to the drier edges marsh reedgrass becomes predominant. Willows will invade into both the sedge and marsh reedgrass dominated meadows. The sedge meadow community is very productive, but the high water table, particularly in the spring when the sedge species are most palatable, restricts livestock movement. One study done in the Yukon found that crude protein on these meadows declined from a high of 10% in May to less than 5% in September (Bailey et al. 1992).

Beaked sedge found in abundance in this community is usually associated with nitrogen rich conditions and moving water (Brierly et al. 1985). Water sedge is often found in abundance in this community type and is associated with calcium rich stagnant water (MacKinnon et al. 1992).

CMA2. Marsh reedgrass meadow

(*Calamagrostis canadensis*)

n=6 This community is found on the edges of sedge meadows and moist draws where the water table is lower. The lower water table makes this community accessible for most of the grazing season. Willow will invade onto these sites to form the Willow/Marsh reedgrass community type. Increased grazing pressure on these sites will cause marsh reedgrass to decline and their will be an invasion of Kentucky bluegrass and dandelion. These sites are highly productive for domestic livestock and should be rated as primary range.

CMA3. Cow parsnip/Kentucky bluegrass-Marsh reedgrass

(Heracleum lanatum/Poa pratensis-Calamagrostis canadensis)

n=1 This community type is found on fine textured, silty soils adjacent to the Willow river near Wabasca . It represents a Willow/Cow parsnip/Marsh reedgrass community that has been cleared and then grazed extensively. The heavy grazing pressure has allowed dandelion and Kentucky bluegrass to invade onto the site. The high nutrient and moisture regime of this community type makes it extremely productive. Once cleared of shrubs it can provide a significant amount of forage for domestic livestock.

CMA4. Snowberry/Kentucky bluegrass

(Symphoricarpos occidentalis/Poa pratensis)

n=4 This snowberry dominated community type appears to be common on level, well drained, gravelly areas along rivers throughout Northern Alberta. In the absence of disturbance this community type appears to be dominated by snowberry, rose, fireweed, slender wheatgrass and marsh reedgrass. Heavy grazing pressure causes the native forbs and grasses to decline and allows Kentucky bluegrass, dandelion and clover to increase. Because these clearings are some of the only natural openings throughout the Central Mixedwood they tend to be heavily utilized by livestock. Snowberry which is unpalatable to livestock will remain even under extreme grazing pressure.

CMA7. Willow/Sedge

(*Salix spp./Carex spp.*)

n=6 This community type is found along the edges of sedge meadows and in moist depressions. Willow becomes established at the edges of the sedge meadows due to the shorter duration of standing water. Increased flooding and prolonged waterlogging may result in the disappearance of willow and a transition to a water sedge meadow.

These sites are fairly productive but difficult to graze due to the moist ground conditions and heavy shrub cover which reduces access and mobility within the area.

CMA11. Willow/Fireweed

(Salix spp./Epilobium angustifolium)

n=1 This community type represents a 3 year old burn of a white spruce forest. Fireweed and marsh reedgrass early successional species quickly dominate the community after a fire. As this community undergoes succession the herbaceous understory will be suppressed as a result of shading by white spruce. Eliminating the tree canopy cover has increased the forage production of this site from 50-100 kg/ha under a spruce/moss forest to over 1700 kg/ha on this community type.

CMA12. Willow-Spruce/Kentucky bluegrass

(Salix spp.-Picea glauca/Poa pratensis)

n=1 This community represents an old spruce community which burned in 1968, succeeded to willow, and is now succeeding back to white spruce. After the fire, the canopy was opened up allowing for good forage productivity. Consequently, cattle grazing was quite heavy allowing Kentucky bluegrass and clover to establish. Thistle is now beginning to invade and will expand to other areas if not controlled. As the spruce continues to mature, the increasing canopy cover will cause a decline in overall production and this site will eventually become non-use for domestic livestock.

CENTRAL MIXEDWOOD SUBREGION

TAME FORAGE COMMUNITIES

Photo 8. This range improvement clearing exhibits signs of heavy grazing pressure and is slowly being invaded by tall buttercup.

CM - TAME FORAGE COMMUNITIES

(Cleared areas that have been broken and seeded to tame forage)

Throughout the Central Mixedwood subregion there are sites that have been deforested, broken, and seeded to tame forage. Usually these areas are mesic and moderately well to well drained with good nutrient levels. Because most of these tame forage stands are established on similar sites, the most influential factors affecting plant species composition are stand establishment and grazing regime.

Stand establishment is important because it determines what the initial plant species composition is going to be. Seed bed preparation and the type of seed sown are the two most important factors influencing stand establishment. Seed bed preparation is important because it helps to determine how well the sown seed germinates and establishes. If the seed bed is not well prepared the tame forage stand may establish poorly and native species can become a dominant component of the plant community. If the seed bed is well prepared, the community type that establishes will depend on the type of seed sown. If a mixture of Creeping Red Fescue, Timothy, and Alsike Clover is sown into the area a Creeping Red Fescue/ Alsike Clover community type will become established. Whereas, if a mixture of Smooth Brome Grass, Timothy, Creeping Red Fescue, and Red Clover is sown, a Smooth Brome/ Red Clover community type will become established.

After the stand is established, the grazing regime applied to the stand will determine the plant species composition. Generally, a light to moderate amount of grazing allows the stand to maintain itself while sustained heavy grazing causes the stand to degrade. Damage to a stand due to over grazing occurs more readily while the stand is establishing than it does when the stand is established. This is because the forage plants in an establishing stand have not had time to develop energy reserves in their roots, and are therefore, more susceptible to grazing induced damage.

Well distributed light to moderate grazing will normally maintain a forage stand similar to what was seeded on the site. These stands are generally the most productive and provide the best grazing opportunities for livestock. They are normally considered to be in good to excellent range condition. Non use or very light grazing often results in the stand becoming dominated by the forage species that is most competitive under an ungrazed situation. Plant community changes which occur under heavy grazing are dependent on the grazing history (level of use, season of use and duration of the grazing regime). Overgrazed community types develop over a long period of repeated overgrazing. If weedy species such as Tall Buttercup, become established on overgrazed sites, they can quickly become a dominant species.

Tame grass plant communities

Key to tame forage communities in the Central Mixedwood subregion

CMB1. Kentucky bluegrass/Dandelion

(Poa pratensis/Taraxacum officinale)

n=8 This community type has had a history of being grazed heavily throughout the growing season. Heavy grazing throughout the growing season, allows Kentucky bluegrass, clover, and dandelion to out-compete all of the other vegetation. This community occurs on tame pastures or native rangeland that has been over grazed. It is considered to be in poor condition because forage production and nutritional value have been degraded

CMB3. Timothy/Dandelion

(Phleum pratense / Taraxacum officinale)

n=1 This community type develops on sites that were seeded with a timothy, meadow foxtail, clover mixture. Timothy establishes very quickly on pastures that have been recently seeded. If this pasture had been seeded with creeping red fescue and smooth brome they eventually will outcompete timothy and this community will likely become dominated by creeping red fescue and smooth brome. Timothy provides excellent forage for domestic livestock, especially if timothy is kept in the vegetative state by mowing or grazing.

CMB7. Smooth brome

(*Bromus inermis*)

n=2 This community type occurs on cleared pastures that were seeded with a smooth brome, timothy-clover mix. With a moderate grazing regime, smooth brome grass is the most competitive forage plant seeded into this site. It outcompetes timothy because it is strongly rhizomatous and is able to fill in the gaps between plants allowing it to shade out the timothy. One of the sites had only been recently cleared and the forage species had not yet fully established. As a result, forage production was only 1/3 as high as expected.

CENTRAL MIXEDWOOD SUBREGION

DECIDUOUS FOREST COMMUNITY TYPES

Photo 9. Aw/Rose/Clover community type represents an deciduous community that has been moderately to heavily grazed for a number of years.

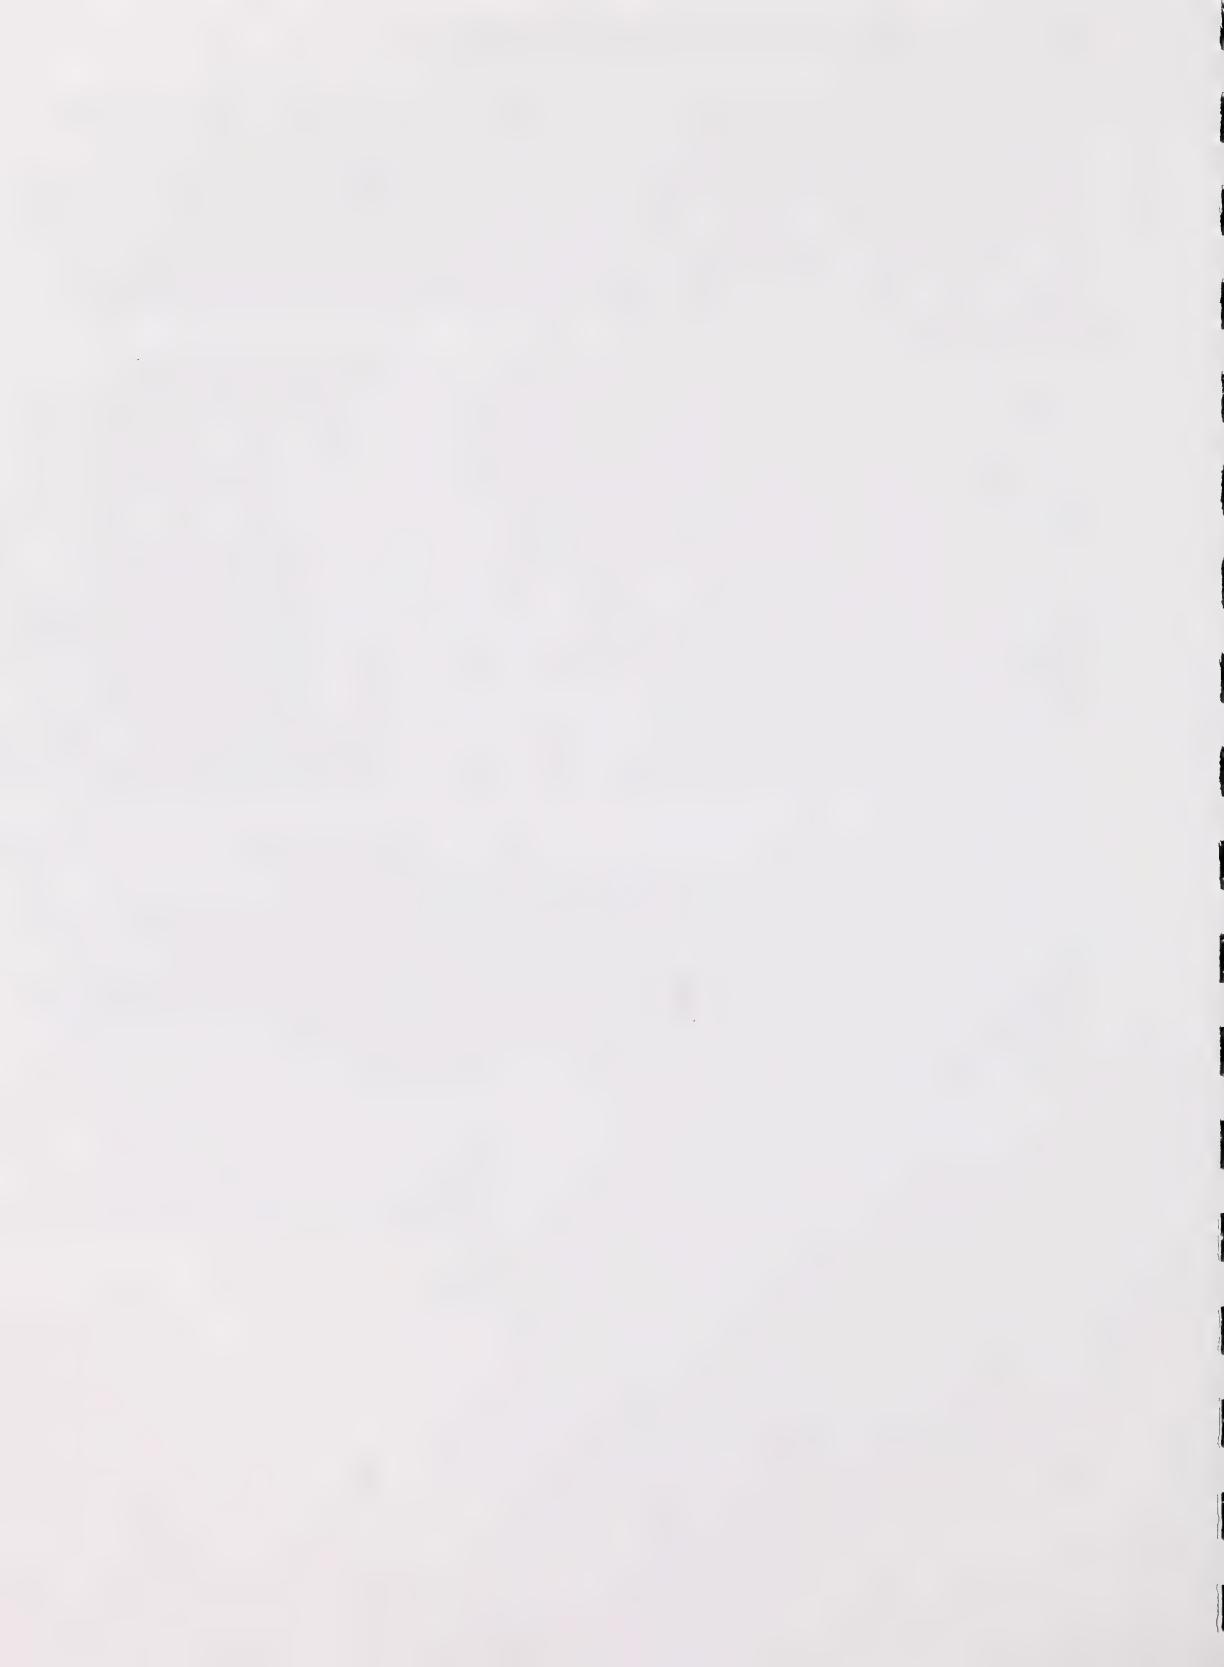

CM - DECIDUOUS FOREST COMMUNITIES

Balsam poplar is most commonly found on moist upland and alluvial bottomland sites; its best growth is on moist rich bottomlands with deep soil (Peterson and Peterson 1992). The nine stands with predominant balsam poplar (Pb) cover represent three community types in the Central Mixedwood subregion. The Pb-Aw/River alder community is found on lower slope positions and stream channels where there is seepage throughout the growing season. The Pb/Rose-Alder and Pb-Aw/Beaked hazelnut-Rose community types are found upslope on slightly drier and better drained soils. These two community types integrate into the Aw/Rose dominated community types on mesic/medium ecosites.

White birch is indicative of well-drained, sandy or silty loams (Wilkinson 1990). In Alberta this tree is found in association with balsam poplar on moist sites adjacent to small creeks and lowland areas. Pure stands of Alaska variety white birch are also found on dry sandy ridges with high watertables throughout northern Alberta. Beckingham (1993), found that white birch was well adapted to growing on a soil with a pH of less than 5.3. The White birch/Willow dominated community type maybe indicative of sites with slightly lower pH's.

More mesic sites tend to be dominated by aspen and rose. It is the underlying soil conditions and site history that appear to dictate which forb and shrub species will dominate these mesic sites. Blueberry and twinflower appear to indicate sandy soils with poorer nutrient regimes. An abundance of tall forbs (Aw/Rose/Tall forb) appears to be indicative of higher nutrient regimes that have not been disturbed by livestock. In contrast the low forb (Aw/Rose/Low forb) dominated type occupies sites similar to the tall forb type, but these sites appear to have been disturbed by livestock. Increased grazing pressure on these two community types leads to the formation of strawberry and clover dominated community types (Pb-Aw/Rose/Strawberry, Aw/Rose/Clover).

Sites that have a more subhygric moisture regime and are moderately well-drained tend to be dominated by willow and alder (Aw/Alder-Willow-Rose, Aw/Willow). The Aw/Rose-Saskatoon community was described on south and west facing slopes overlooking streams and rivers. This community is very similar to the community that was described in the Dry Mixedwood subregion. On sites with rich nutrient regimes red osier dogwood and horsetail dominated communities are very common. The Aw/Horsetail community is usually found on moister sites than the Aw/Red osier dogwood-Rose community type.

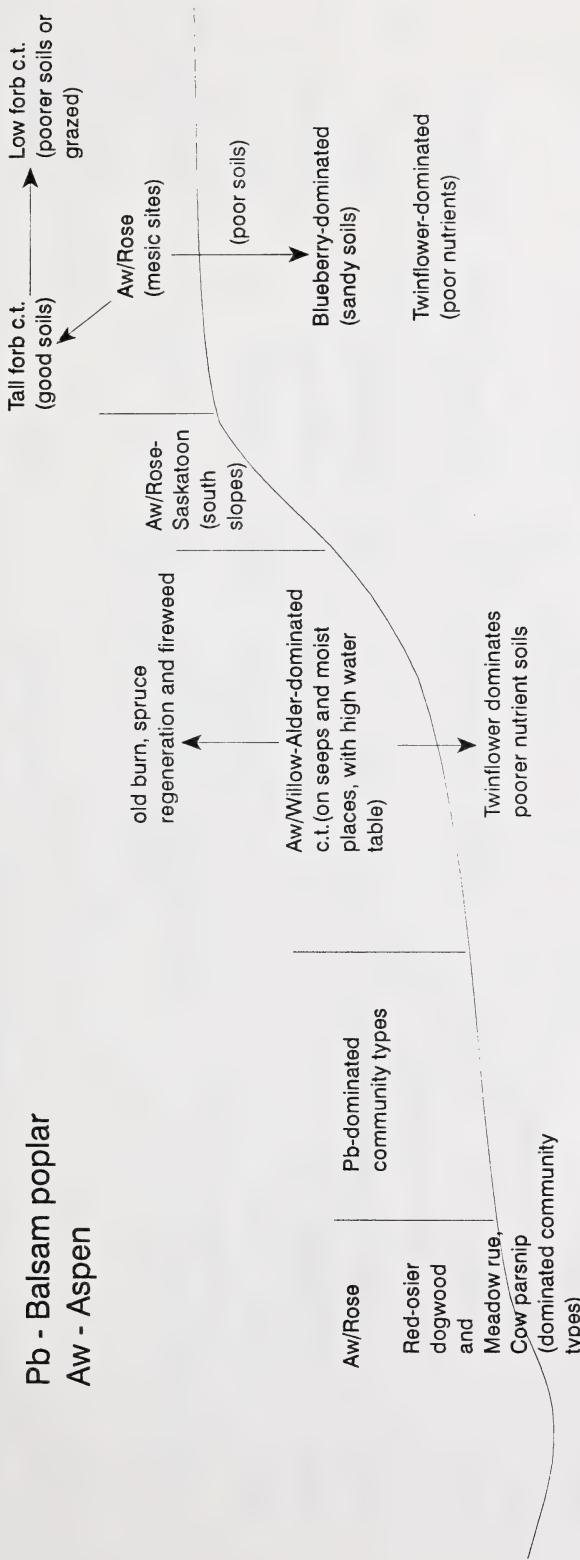

Figure 4. Sequence of Aspen/Rose-dominated community types in the landscape of the Central Mixedwood subregion.

Key to Aspen/Rose community types in the Central Mixedwood subregion

CMC1. Pb/Rose-Alder

(Populus balsamifera/Rosa acicularis-Alnus crispa)

n=3 This community was found on moderately well-drained sites with subhygric moisture regimes. Beckingham (1993), described a similar community type. He found these forests to develop on parent materials that are neutral to alkaline, thus they tended to have a relatively high level of nutrient availability and potentially high production levels.

This community is producing only a moderate forage base for domestic livestock. Green alder, which makes a large part of the total forage production for this vegetation type, is generally unpalatable to livestock. This community type would be rated as secondary or non-use range.

CMC2. Pb-Aw/River alder

(Populus balsamifera-Populus tremuloides/Alnus tenuifolia)

n=3 This community type is found on moist lower slope positions. A similar community type was described on similar sites in the Lower Foothills subregion (Willoughby and Downing 1995). The high cover of alder limits the light reaching the understory and results in low production of grass and forbs. The majority of the total forage production comes from alder which is generally inaccessible and unpalatable to livestock. Consequently this community type would be rated as non-use for domestic livestock.

ENVIRONMENTAL VARIABLES

CMC3. Pb-Aw/Beaked hazelnut-Rose

(Populus balsamifera-Populus tremuloides/Corylus cornuta-Rosa acicularis)

n=2 This community type was described on south facing slopes and is very similar to the beaked hazelnut communities described in the Dry Mixedwood subregion. This type appears to occupy warmer and drier microsites that resemble the Dry Mixedwood's climate. The total production of this type is high, but the majority of production is coming from hazelnut which is largely unpalatable to livestock at proper stocking levels. The high cover of hazelnut also restricts access to livestock, limiting the forage availability. This community would be rated as secondary range.

CMC4. Bw/Willow

(Betula papyrifera/Salix spp.)

n=1 This community type was described on a very moist site that was burned or cleared and is now undergoing succession to a paper birch dominated community type. The understory of this community type is dominated by sphagnum moss, which is characteristic of the poor fen ecosite described by Beckingham and Archibald (1996). The site was likely dominated by black spruce and larch prior to disturbance. The poor nutrient status and very moist conditions make this community type unsuitable for livestock grazing. This community type should be rated as non-use.

CMC5. Aw/Blueberry

(Populus tremuloides/ Vaccinium myrtilloides)

n=4 This is a very dry, well-drained community type with sandy soil. It is found in conjunction with jack pine stands. Productivity of shrubs is largely blueberry, which is unpalatable to livestock.

These stands tend to be relatively open allowing for easy access by livestock, but the dry site conditions and poorer nutrient status limit the amount of regrowth after grazing. If this community type is managed for one rotation a year, it can contribute significantly to the overall carrying capacity of a lease.

ENVIRONMENTAL VARIABLES

CMC6. Aw/Rose/Twinflower

(Populus tremuloides/ Rosa acicularis/Limnaea borealis)

n=6 This community type has been grazed moderately to heavily and is very similar to the grazed Pb/Rose/Strawberry and Aw/Rose/Low forb community types. Grazing pressure reduces the cover of shrubs and tall-growing forbs and allows the low-growing forbs to increase in cover. This community type occupies soils with poor nutrient regimes. The poor nutrient status appears to favour the growth of twinflower, a species that is well adapted to growing on poor soils (Cornis and Annas 1986). This may explain why twinflower is predominant on this community type and not on the other grazed community types.

CMC7. Aw/Rose/Low forb

(Populus tremuloides/Rosa acicularis/Low forb)

n=14 This type occupies mesic, well-drained sites with medium nutrient regimes. This type is similar to the Aw/Rose/Tall forb community type, but this type appears to occupy drier sites with poorer nutrient regimes. It has also been observed that this type can also be produced when the tall forb community is grazed for a number of years. The increased grazing pressure may explain why the production on this type is lower than the tall forb type.

Forage production in this type is good, but the low-growing forbs are not as accessible to livestock as the tall growing forbs. Despite these limitations this community type should still be rated as primary range.

CMC8. Aw/Rose/Tall forb

(Populus tremuloides/Rosa acicularis/Tall forb)

n=13 This type appears to be the modal aspen community type in the absence of disturbance on mesic, medium to rich sites. The presence of tall forbs wild sarsaparilla, fireweed, and peavine distinguish this community from the low forb type. It is unclear why there is a difference in the tall and low forb types. Corns and Annas (1986) recognized the two types in the Lower Foothills subregion. They felt the wild sarsaparilla type was moister and had a higher nutrient regime. It has also been observed that the low forb type can be produced when the tall forb community is lightly to moderately grazed for a number of years (Willoughby 1996).

The forage production on this community type is good. The majority of the vegetation is palatable to livestock. This community type would be rated as primary range for domestic livestock. Wild sarsaparilla, a major component of this community type appears to be very sensitive to any disturbance by livestock.

CMC9. Pb-Aw/Rose-Saskatoon

(Populus tremuloides/Rosa acicularis-Amelanchier alnifolia)

n=2 This community type is found on mesic, well drained south facing slopes that overlook rivers and creeks. This community is also similar to the Aw/Saskatoon-Rose community that was described in the Dry Mixedwood subregion. Both community types occur on south and west facing slopes. Saskatoon provides important browse for wild ungulates. Livestock also find saskatoon palatable and in areas where there is extensive cattle grazing this species can be heavily browsed.

CMC10. Aw-Pb/Rose/Strawberry

(Populus tremuloides-Populus balsamifera/Rosa acicularis/Fragaria virginiana)

n=4 This community type appears to have been moderately grazed in the past. As grazing pressure becomes heavy, there is a reduction in shrub, tall forbs and native grass cover and an increase in cover of low growing forbs(dandelion and strawberry). Continued heavy grazing pressure eventually leads to a decline in all native plants and Kentucky bluegrass, clover and dandelion will predominate in the understory (Willoughby 1996). The forage production on this community type is only moderate and is slightly less than other Aw and Pb dominated community types. A period of rest would greatly benefit the production on this community type.

CMC11. Aw/Rose/Clover

(Populus tremuloides/Rosa acicularis/Trifolium spp.)

n=1 This community type is represented by aspen stands that have received moderate to heavy grazing pressure for a number of years. As a result, native forbs have declined and clover has increased in the understory. A small portion of the original shrub and tall forb understory still remains. Although, grass production has dropped, forb production remains high due to the dense cover of clover. This community has not been grazed as long as the Aw/Kentucky bluegrass/Clover community type (Willoughby 1996).

CMC12. Aw/Alder-Willow-Rose

(Populus tremuloides/ Alnus crispa-Salix spp.-Rosa acicularis)

n=13 This community type is scattered throughout the Central Mixedwood subregion on mainly mesic to subhygric, well-drained sites. This community is likely of fire origin. Many of the plots were described from a large fire that burned through the area in 1968. The aspen trees are also young and very dense. The high cover of aspen, alder, and willow limits the amount of light reaching the understory. Consequently, there is little forage available for domestic livestock. This community type would be rated as secondary or non-use range.

CMC13. Aw/Willow

(Populus tremuloides/Salix spp.)

n=4 This community type is similar to the Aw/Alder-Willow-Rose community type, but lacks the cover of alder. Previously, this community type was split into four community types (Willoughby and Downing 1995). These included the Aw/Willow-Rose/Twinflower, Aw/Willow-Rose/Bunchberry, Aw/Rose-Willow-Pin cherry/Fireweed and Aw/Rose-Willow-Saskatoon. All four community types appeared to have had a fire origin, but had slightly different moisture and nutrient regimes which affected forage productivity. Productivity varied from 1326 to 1306 kg/ha on the Aw/Willow-Rose/Bunchberry and Aw/Rose-Willow-Pin cherry/Fireweed types to 606 kg/ha on the Aw/Willow-Rose/Twinflower type. Because the sample size was so small it was felt to be impractical to split the four community types and they were lumped into this one type for the purpose of this guide. As this community undergoes succession forage productivity will decline.

CMC14. Aw/Red osier dogwood-Rose

(Populus tremuloides/Cornus stolonifera-Rosa acicularis)

n=4 This community is typical of river floodplains throughout the Central Mixedwood subregion. This community has a subhygric moisture and rich nutrient regime. Beckingham and Archibald (1996) found this community type on mid to lower slope topographic positions or near water courses where they receive nutrient-rich seepage or flood waters for a portion of the growing season. This community type is one of the most productive in the Central Mixedwood, but the high cover of shrubs limits access to livestock. The high cover of tall growing shrubs (alder, red osier dogwood) also limits the growth of low shrubs, forbs and grass the principle forage species for domestic livestock in deciduous forests. As a result, this community should be rated as secondary or non-use range.

CMC15. Aw/Horsetail-Cow parsnip

(Populus tremuloides/Equisetum arvense-Heracleum lanatum)

n=1 This community type occupies lowland sites adjacent to black spruce and willow lowlands. It is very moist and nutrient rich. Horsetail types in other subregions also tend to be moister and richer than the modal Aw/Rose types. This site is very productive and produces a large amount of forage for domestic livestock. Horsetail is generally unpalatable to livestock and can be poisonous to horses. In contrast cow parsnip is very palatable to livestock. This community type would therefore be rated as primary or secondary range for domestic livestock.

CENTRAL MIXEDWOOD SUBREGION

CONIFEROUS AND MIXEDWOOD FOREST COMMUNITIES

Photo 10. The Balsam fir-White spruce/Moss community type is the climatic climax community for the Central Mixedwood subregion.

CM-CONIFEROUS AND MIXEDWOOD FORESTS

The mixedwood and coniferous community types described in this guide represent five ecosites as described by Beckingham and Archibald (1996). On sites with subxeric moisture and poor nutrient regimes, coarse textured, sandy soils open stands of jack pine generally dominate (Pj/Alder, Pj/Bearberry). These community types commonly have a carpet of lichens covering the forest floor and a thin organic layer typically less than 5 cm thick (Beckingham and Archibald 1996).

On slightly moister sites with submesic moisture and medium nutrient regimes aspen grows in conjunction with jack pine to form the Aw-Pj/Bearberry/Lichen community type. The soils of this community type continue to be coarse-textured but the moisture and nutrient conditions are more favourable to the growth of aspen.

The mesic/medium sites are generally dominated by white spruce (Balsam fir-Sw/Moss, Sw/Moss, Sw/Creeping red fescue) and mixedwood communities of aspen and spruce (Aw-Sw/Rose/Low forb). These communities represent the reference ecosite for the Boreal Mixedwood subregion (Beckingham and Archibald 1996). Generally, these sites have moderately fine to fine-textured till or glaciolacustrine parent materials. Pioneer deciduous species (aspen, balsam poplar and birch) are replaced with white spruce and balsam fir as these sites develop successionaly. With succession shade tolerant plants take over the herbaceous layer as conifers dominate the canopy. These shade tolerant species are unproductive and often unpalatable for domestic livestock. Forage productivity declines from 2.3 ha/AUM in a deciduous community to 2.3-8.6 ha/AUM in a mixedwood community to less than 10 ha/AUM in a conifer community.

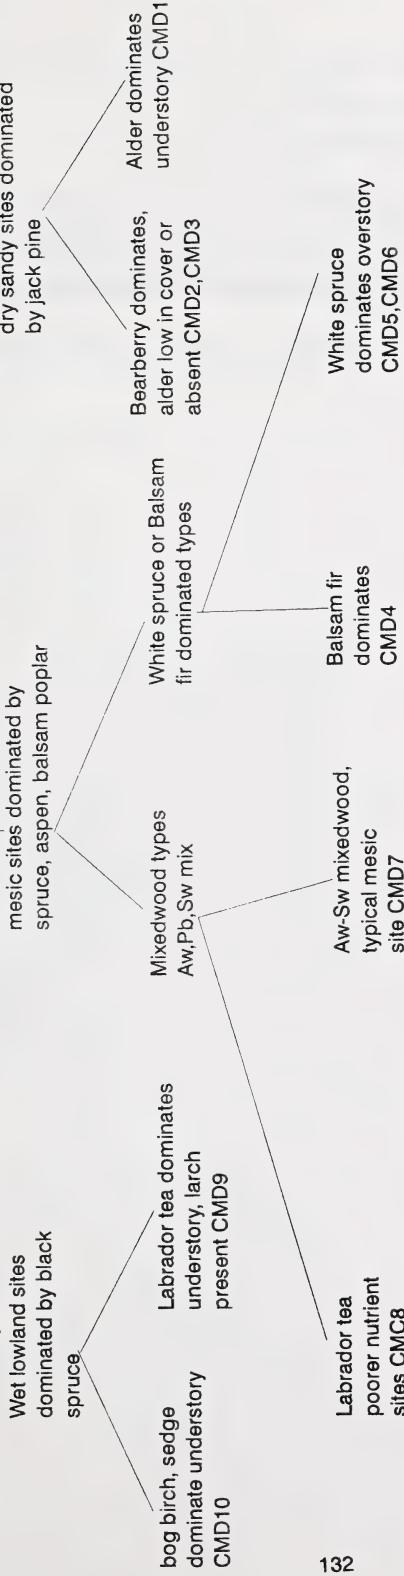

Black spruce and larch communites generally dominate on wetter sites with subhygric to subhydric moisture regimes and poor to medium nutrient regimes to form the Sb/Bog birch and Sb/Labrador tea/Moss community types. Larch is more tolerant of excessive moisture and is indicative of an enriched nutrient status, while black spruce is typical in areas of stagnating ground water with poor nutrient status (Hay et al. 1985). Generally, these community types are considered non-use for domestic livestock.

Beckingham and Archibald (1996), provide a good description on how the conifer and mixedwood community are arranged in the landscape.

Table 9. Conifer and Mixedwood communities of the Central Mixedwood subregion

Community number	Community type	Productivity (kg/ha)	Ecosite	Carrying capacity (ha/AUM)	
		Grass	Forb	Shrub	Total

CMD4. Balsam fir-Sw/Moss

(Abies balsamea-Picea glauca/ Moss)

n=1 This is a mature balsam fir forest which represents the climax vegetation for the area. The northerly aspect of this community type has probably protected the site from past disturbance by fires and allowed the community to undergo succession. The high canopy of balsam fir and spruce limits the light reaching the forest floor, limiting the growth of grasses and forbs. As a result, the forage productivity of this community type is very low. This community would be considered non-use.

CMC8. Aw-Sw/Labrador tea/Moss

(Populus tremuloides-Picea glauca/Ledum groenlandicum/Moss)

n=1 This community type has relatively poor nutrient status. Labrador tea and bog cranberry are indicative of acidic soil surface soil conditions. Beckingham and Archibald (1996) described this ecosite with a jack pine and black spruce dominated overstory. The moisture and nutrient conditions of this community type are probably better than there ecosite, which allows aspen and white spruce to dominate the overstory, but the soil conditions are poorer than the Aw-Sw/Rose/Low forb community type. This community type does not produce much palatable forage and therefore would be classified as non-use.
